1. INTRODUCTION

This appendix presents the background analyses conducted by Teck American Incorporated (TAI) to support the baseline ecological risk assessment (BERA) for Operable Unit 1 (OU) 1 and OU 2 (the Aquatic BERA) of the Upper Columbia River (UCR) site (hereinafter, the Site[1]; see Map C-1). It includes background analyses for metals and metalloids in sediment and porewater. An assessment of background concentrations of metals and metalloids in upland soils for the Site have been previously developed as described in the technical memorandum that was approved by The U.S. Environmental Protection Agency (EPA) in 2020 and is used in the relict floodplain deposition area (RFDA) and windblown sediment deposition area (WSDA) BERA (Volume 4 of the main document). The soil background assessment technical memorandum is included as Attachment C1 to this appendix and briefly discussed in Section 3 of this appendix.

Background concentrations of substances in environmental media have been defined by USEPA (2002b) as the substance concentrations in constituents or locations that are not influenced by releases to the Site. This may include either naturally occurring or anthropogenic substances. Naturally occurring substances are present in the environment in forms that have not been influenced by human activity (e.g., metals naturally occur in the bedrock, sediments, and soils). Anthropogenic background (also known as "area background" [Washington Administrative Code 173-340-200]) includes substances that are present in the environment as a result of human activities but are not specifically related to the release in question. Thus, background can be considered a range of concentrations that includes both natural and area background.

Characterization of background concentrations in the environment is an important part of the remedial investigation and feasibility study (RI/FS) and risk assessment process (USEPA 2018) and is described in several federal and state guidance documents (U.S. Navy 2003; USEPA 1995; USEPA 2002b,c; Ecology 2019b). For the UCR Site, development of a background data set was first described in the Statement of Work for the 2006 UCR Site RI/FS Settlement Agreement (USEPA 2006a). The UCR Site RI/FS Work Plan (USEPA 2008) provided further detail on page 2-7, where the importance of characterizing background concentrations as part of the site characterization is described:

> The UCR RI/FS will include a series of field investigations to collect site characterization data (e.g., physical and ecological settings, sources of contamination, nature and extent of contamination, and background conditions) in order to make informed decisions about the level of risk presented by the site and the appropriate type(s) of remedial action that may be required.

[1] As per the June 2, 2006, Settlement Agreement for Implementation of Remedial Investigation and Feasibility Study at the Upper Columbia River Site (referred to herein as the UCR Site or Site), the Site consists of the areal extent of hazardous substances contamination within the United States in or adjacent to the Upper Columbia River, including the Franklin D. Roosevelt Lake, from the U.S.-Canada border to Grand Coulee Dam, and all suitable areas in proximity to such contamination necessary for implementation of the response actions (Remedial Investigation and Feasibility Study) described therein (USEPA 2006a).

The RI/FS Work Plan (USEPA 2008) also recognized that assessment of background conditions would be required to better understand the nature and extent of contamination, as will be evaluated in the Aquatic RI report.

This appendix presents the analyses conducted to establish background threshold values (BTVs[2]) and BTV hazard quotients (HQs) from the background data set for sediment (Section 2) and field-collected porewater (Section 4) to support the risk characterization in the Aquatic BERA. A refined analysis or discussion of background may be included in the Aquatic RI report.

[2] A background population parameter representing an upper threshold, in this case the 95 percent upper tolerance limit (UTL) with 95 percent coverage (95/95 UTL).

2. SEDIMENT BACKGROUND

Data visualization and multivariate statistical techniques were used to characterize sediment background. This section describes the approach and findings for the sediment BTVs, including the preparation of the data set, exploratory data analyses, multivariate analyses, and calculation of the BTVs.

Due to the large size of the UCR Site, there is significant variability in hydrological, geological, and biological conditions from north to south. While there are some regional background samples available from smaller tributaries in the watershed, as well as some samples from the Columbia River north of Trail, British Columbia, it is unclear whether these are sufficient to characterize the varied background conditions at the UCR Site. It is also likely that not all sediment samples in the UCR are impacted by smelter releases, and that there are locations where chemical concentrations in river sediments are reflective of background conditions. Therefore, a comprehensive sediment data set was compiled with the objective of using multivariate statistics to identify samples characteristic of background.

Multivariate statistical techniques consider suites of constituent concentrations concurrently and are often more powerful than univariate or bivariate techniques that look at data analyte by analyte. This study used a variety of visualization tools and multivariate statistical techniques (e.g., principal component analysis [PCA]) to identify unique chemical signatures associated with sediments and to identify a signature indicative of background. To objectively classify all the samples according to their unique signatures, a cluster analysis was done that partitioned the data into statistically defensible groups. The reliability and validity of these clusters were then assessed using multiple techniques. Those samples that were classified as the background cluster are used to develop BTVs.

2.1 SEDIMENT BACKGROUND ANALYSIS DATA SET

A comprehensive sediment data set was evaluated to identify sediment samples representative of background conditions, and included samples from: 1) the mainstem Columbia River between the Grand Coulee Dam and the U.S.-Canada border, 2) the mainstem Columbia River in Canada north and south of Trail, British Columbia, and 3) tributaries to the Columbia River. This evaluation began with a compilation of a comprehensive sediment data set from available data sources, including those contained in the UCR Site RI/FS project database (https://teck-ucr.equisonline.com/), as well as historical documents. The studies included in the comprehensive data set are listed in Table C-1.

2.1.1 DATA EXCLUSION/INCLUSION CRITERIA

Exclusion and inclusion criteria were applied to the comprehensive data set to produce the data set used for analysis. There were three steps in the process for developing and applying these criteria:

1. **Apply general exclusion criteria relating to sample matrices, locations, and collection/analytical methods.**

In the first step, a set of general data exclusion criteria were applied to all studies to facilitate comparability across data sets:

- Soil data were excluded; only samples labeled as sediment from the Columbia River and its tributaries were retained.
- Results for samples prepared using total digestion[3] methods were excluded; this represents a negligible reduction in sample size.
- Results from acid-volatile sulfide/simultaneously extracted metals analysis methods were excluded to facilitate comparability across analytical results.
- Results from studies or sample analyses performed using only the very fine fraction of the sediment matrix were excluded. These include bulk sediment chemistry performed on beach sediment samples specifically collected for human health risk assessments, which were performed on the less than 250 micrometer sieve fraction, and other sediment samples sieved to 150 micrometers.

2. **Identify the list of metals to include in the multivariate analysis by considering the frequency of analysis and frequency of detection for individual metals across all studies and applying a cutoff for detection frequency.**

   For the second step, the samples remaining after the general exclusion criteria (from the first step) were reviewed for the number of metal analytes reported and detected for sediment samples. The list of metals evaluated included the Target Analyte List[4] plus molybdenum. The percent coverage (the frequency that a metal was analyzed) and detection frequency were calculated for each analyte. These statistics were reviewed to identify which metals to exclude from the multivariate analysis due to either infrequent analysis (low percent coverage) or high proportion of nondetected results (low detection frequency). A cutoff criterion for detection frequency was selected by plotting the numbers of samples included and excluded as a function of detection frequency, and visually assessing what criterion allowed for the inclusion of as many samples as possible while, at the same time, achieving a close-to-complete data set consisting of detected results. A cutoff criterion of 75 percent analyte detection frequency was identified and used to exclude metals exhibiting a high proportion of nondetected results across samples. Antimony, selenium, silver, and thallium were excluded because they were either infrequently analyzed across the data sets or had low detection frequencies. Molybdenum was also excluded from the multivariate analyses as it was analyzed in only a very small subset of sediment samples in the data set (less than 1 percent of samples).

   Based on the screening completed in the second step, the following 19 metals met the inclusion criteria and were retained for the multivariate analysis:

[3] Total digestion methods (e.g., a four-acid procedure including hydrofluoric acid) are capable of dissolving mineral grains and mobilizing relatively high concentrations of certain metals (e.g., aluminum and potassium).

[4] Target Analyte List metals include aluminum (Al), antimony (Sb), arsenic (As), barium (Ba), beryllium (Be), cadmium (Cd), calcium (Ca), chromium (Cr), cobalt (Co), copper (Cu), iron (Fe), lead (Pb), magnesium (Mg), manganese (Mn), mercury (Hg), nickel (Ni), potassium (K), selenium (Se), silver (Ag), sodium (Na), thallium (Tl), vanadium (V), and zinc (Zn).

Aluminum	Cobalt	Nickel
Arsenic	Copper	Potassium
Barium	Iron	Sodium
Beryllium	Lead	Vanadium
Cadmium	Magnesium	Zinc
Calcium	Manganese	
Chromium	Mercury	

3. **Exclude samples that did not include all metals identified in step 2.**

   For the third step, studies or samples where the full list of 19 metals was not analyzed were removed from the data set.

Table C-1 presents the number of samples from each study that met inclusion criteria and that were included in the sediment background analysis data set (n = 1,641 samples). All the samples included in the sediment background analysis data set are provided in Attachment C2 and shown spatially in Map C-2a through Map C-2l.

2.1.2 DATA HANDLING

Data management was performed in accordance with the UCR Final Data Management Plan (DMP) Amendment No. 1, 2019 (TAI 2019). The following sections outline data handling specific to this analysis, including nondetected values, field duplicates, and grain size.

Nondetected results are statistically known as "left censored" measurements because the concentration of a nondetected result falls somewhere between zero and the reporting limit. USEPA (2015) offers a number of options for handling nondetected results, including Kaplan-Meier estimators, Regression on Order Statistics, and replacement with surrogate values. In the PCA analysis, nondetected values were substituted with the reporting limit, as recommended in the DMP (TAI 2019). Handling of nondetected values for BTV calculations was performed by ProUCL.

Field duplicates and replicates were treated following the procedure outlined in the DMP, as described in Section 3.3 of Volume 1 of the Aquatic BERA.

2.2 ANALYSIS APPROACH

This section describes the approach to the sediment background analysis, including multivariate analyses such as PCA, cluster analysis, and the statistical methods for calculating BTVs.

2.2.1 PRINCIPAL COMPONENT ANALYSIS AND CLUSTER ANALYSIS

This section describes the methods and uncertainties for the PCA and cluster analysis.

PCA aids understanding of complex patterns in multivariate data that are often difficult to detect with univariate techniques by reducing the multivariate data into their dominant patterns (Jolliffe and Cadima 2016). PCA results can be visually segregated to group individual samples based on the relative similarity or dissimilarity of their underlying data. In the sediment background analyses, samples that plot close to each other in multivariate space have relatively similar metals "fingerprints" compared to samples that plot farther away from each other. From a technical

perspective, PCA is a data reduction technique that projects multivariate data onto a smaller dimensional space. Much like the shadow of a tree, the two-dimensional image projected on the ground is a simplification of the three-dimensional form but provides key information, such as the overall shape, that can be used to identify the type of tree (e.g., palm tree or conifer). Similarly, PCA allows data containing a large number of correlated variables (e.g., multiple metal concentrations) to be summarized by a smaller number of uncorrelated variables, called principal components (PCs) that capture key information in the data and can be used to distinguish unique fingerprints. The PC loadings reflect the relative contribution or importance of each variable on each PC. PC loadings are the correlation coefficients for the relationship of individual variables with the PCs and provide the basis for interpreting the underlying construct measured by each PC. Using the tree example again, the loadings would indicate how important the tree biomass, diameter, and height are for defining each PC. The objective of the PCA was to identify multivariate signatures of different sources (e.g., smelter, other sources, geogenic).

Clustering is a technique used to group data points into distinct categories. Hierarchical clustering is among the most common machine learning methods for clustering. In a hierarchical cluster analysis, the distance between samples—in multivariate space—is calculated, and samples are grouped with the nearest or "most similar" samples. This process of grouping samples and re-calculating the distance between remaining samples is repeated until all data points have been combined into a single cluster. This clustering process is commonly visualized in a tree-like graph structure, called a dendrogram, which displays the distance between each sample pair and the resulting clusters. Quantitative or semi-quantitative methods can then be used to determine the optimal number of clusters. A hierarchical cluster analysis was performed on the PCA outputs to identify samples with similar multivariate chemical fingerprints.

2.2.1.1 METHODS FOR PRINCIPAL COMPONENT ANALYSIS

The essential first step in PCA is a thorough exploratory data analysis. PCA is based on an eigenvalue decomposition of the correlation matrix that enables the "projection" of the data as with the tree shadow example above. Standard analyses use the Pearson correlation coefficient and are therefore appropriate for summarizing variables with strong linear relationships; however, the Pearson correlation coefficient does not capture curvilinear relationships. Correlation coefficients are sensitive to outliers, so transformations of the data are often required to achieve linear relationships among variables. A good graphical analysis can guide transformations that are useful for linearizing curvilinear relationships and normalizing skewed data. Graphical techniques also provide a means for assessing the impact of missing data, imputations, and detection limit substitutions.

Incomplete data can have a large impact on PCA results, so thorough investigation of the spatial or temporal patterns in the missing data is critical. Missing data can drive the PCA results, mask the underlying patterns, and lead to confusing results if persistent data gaps are not identified. In this analysis, each study that contributed a data set was evaluated for data completeness, both for metals and individual sample results (as described in Section 2.1).

All metals concentrations were centered-log-ratio (CLR) transformed prior to running the PCA:

For each sample, $CLR_j = \log\left(\frac{X_j}{g(X)}\right),\ j = 1, \ldots, J$

Where:

- J is the number of components (metals)
- g(X) is the weighted geometric mean of all the components within that sample
- X_j is the untransformed concentration for metal J.

The CLR transformation has a long history of use in compositional data analysis (Atchison 1982, 1994; Reimann et al. 2012). As with a proportional transformation, it removes variance due solely to differences in magnitude of concentration and focuses on differences in the relative concentrations. Unlike a proportional transformation the CLR prevents the development of spurious correlations due to constant summation (all proportions in a sample must sum to 1) and meets the criteria for calculations in Euclidean space (Gloor et al. 2017).

The "compositions" package in R was used to transform all samples into a set of CLR values for each metal. Afterward, each of the metals were scaled to unit variance and centered to a mean of zero to minimize the effects of differences in variance among metals and samples. These standardized values then have their correlation matrix and eigenvalues computed, before finally imputing missing values with zero. By computing the correlation matrix and eigenvalues prior to filling in missing values, it retains the underlying relationships in the data. The variance is also maintained, without being influenced by the imputed values.

In the final step, the metal's means, variances, and loadings that are estimated in the PCA can be saved and used to calculate PC scores for new data. These PC scores may be used in subsequent analyses.

2.2.1.2 VISUALIZATION AND INTERPRETATION OF A PRINCIPAL COMPONENT ANALYSIS

A number of data visualization tools are used to aid the interpretation of the PCA. These include scree plots, PC loading plots, and PC biplots. Loadings of the metals on each PC can be viewed separately to understand the metals composition of samples with relatively high or low scores on a particular PC. For example, a sample with a high PC score is concurrently high in analytes that load positively onto that PC and low in the analytes that load negatively on that PC. This information can be used to interpret the chemical composition of sample scores and is useful when describing the predominant patterns captured in the PCA. In general, metals that have loadings above 0.4 on a PC are considered important enough to be used as part of the interpretation of that PC as they have at least a moderately strong correlation with the component[5] (Guilford 1956).

Each PC captures successively smaller portions of the overall variance of the data so that if all PCs are included in the final solution, 100 percent of the overall variance is captured. A meaningful interpretation of the data can often be captured by including only the first few PCs. Scree plots are

[5] Guilford's rule of thumb uses the following benchmarks to guide interpretation of correlation coefficients (r): < 0.2 is a negligible relationship, 0.2 to 0.4 is a low relationship, 0.4 to 0.7 is a moderate relationship, 0.7 to 0.9 is a high relationship and > 0.9 is a very high relationship.

helpful to visualize the proportion of variance explained, with the bend (often referred to as the elbow) in the scree typically indicating the number of PCs to retain for further analysis.

PCA results are traditionally viewed as biplots where different combinations of the PCs are plotted against each other on x-y plots to give views of different rotations of the data in the multidimensional space. In this sediment background evaluation, samples that plot close to each other in a biplot have relatively similar chemical fingerprints, whereas samples that plot far from each other tend to have relatively dissimilar fingerprints. Vectors are overlaid on these plots to represent the loadings of each analyte on each PC. Longer vectors represent a relatively higher loading on a PC. Finally, points on these biplots can be color-coded according to other important Site information and facilitate further interpretation.

2.2.1.3 METHODS FOR CLUSTER ANALYSIS

Hierarchical clustering on the Euclidean distance matrix of scaled PC1, PC2, and PC3 scores was conducted by means of Ward linkage, using the "vegan"[6] and "stats"[7] packages in R (Oksanen et al. 2022). The optimal number of clusters in a given clustering analysis can be difficult to choose, as there is no agreement on the best method to use. Many methods exist to identify an optimal number of clusters. These methods combine information about intracluster compactness (homogeneity within the cluster) and intercluster isolation (between cluster distance), as well as other factors, such as connectedness, and stability (Gao et al. 2023). Given the lack of agreement on best methodology, the optimal number of clusters was chosen using the consensus of 22 cluster fit metrics as implemented in the "NbClust"[8] package (Charrad et al. 2014). Clusters were examined with PCA biplots and mapped to determine their relative distributions across the Site.

2.2.1.4 VALIDATION AND RELIABILITY OF CLUSTERING RESULTS

Statistical validity generally refers to the extent to which a statistical conclusion is well founded and corresponds accurately in the real world. There are many types of statistical validity that have been applied across disciplines and are well documented in the literature (for examples in the medical and psychology fields, see Kaplan and Saccuzzo 1982). In the context of cluster analysis, it can be thought of as the extent to which samples are accurately classified into relevant groups. Some specific types of validity applicable to this analysis are internal validity, face validity, and external validity.

Various data visualizations and summaries were used to assess the internal and face validity of the cluster classifications. In particular, boxplots and spatial groupings were used to illustrate characteristics of the cluster groupings and to help confirm which cluster represents the background data set. Boxplots of metals concentrations for each cluster were created to compare the distribution of each metal across the clusters. The spatial distribution and aggregation of clusters was illustrated by computing the proportion of each cluster identified for samples in

[6] Vegan v2.6-10 package version with function vegdist(df, method="euclidean")
[7] Stats v4.4.0 package version with function hclust(distance, method="ward.D2")
[8] NbClust v3.0.1 package version, with function NbClust(df, min.nc=2, max.nc=6, distance="euclidean", method="ward.D2", index="all")

different conceptual site model (CSM) units of the UCR Site (shown in Map C-1), the Columbia River north of Trail, British Columbia, and tributaries to the Columbia River.

In addition to validating the statistical results, cluster reliability and sample fidelity was also assessed. A bootstrapping procedure was used for this assessment as follows:

1. For each bootstrap replicate, PC scores were randomly sampled with replacement to obtain a sample size equivalent to the sample size of the original data set (1,641 samples).
2. The hierarchical cluster analysis, with three clusters, was run on the randomly sampled PC scores following the procedure outlined in Section 2.2.1.3.
3. New cluster assignments were mapped to the original assignments using a frequentist approach (e.g., if the majority of newly assigned Cluster 1 belonged to the originally assigned Cluster 3, then the new Cluster 1 was mapped to Cluster 3). This ensured that cluster assignments remained consistent throughout the bootstrapped iterations.
4. The random selected samples and their cluster assignments are saved, and the process was repeated for the next bootstrap replicate. This procedure was repeated a total of 1,000 times.

Cluster reliability is reported as the percentage of samples that change cluster assignments between the original clustering and the bootstrapped cluster group. Additionally, the fidelity of individual background cluster samples is assessed by evaluating how consistently each sample remains within the background cluster across all bootstrapped iterations. Any background cluster samples that have less than 95 percent fidelity were excluded from BTV calculations.

2.2.2 CALCULATION OF BACKGROUND THRESHOLD VALUES

BTVs were calculated as 95/95 UTLs, using ProUCL 5.2 (USEPA 2022). BTVs were calculated using metal concentrations for the samples in the background cluster identified using the PCA and clustering as described above. The input and output files for the statistical calculations in ProUCL are provided in Attachment C2 for the sediment BTVs.

Antimony, selenium, silver, and thallium had BTVs calculated, even though they were excluded from the PCA due to low sampling and detection frequencies. For each of these four analytes, no imputed values were used in the BTV calculations, and all nondetected samples that exceeded the maximum detected value for the respective analyte were removed before the 95/95 UTLs were calculated.

2.3 FINDINGS

This section presents the findings of the sediment background analysis. This includes exploratory analyses, PCA, cluster analyses, and the calculation of BTVs.

2.3.1 PCA RESULTS

The first three PCs captured 75 percent of the variability in the multivariate data. The scree plot (Figure C-1) suggested inclusion of additional PCs would not add substantially more information. The following sections describe the PCA results and place them into context with the CSM.

2.3.1.1 LOADINGS

The loadings of each metal were plotted from low to high for each of the first three PCs to identify which metals create the greatest separation of the chemical fingerprints in each dimension (Figure C-2). Loadings are purple and yellow for values below -0.5 and above 0.5, respectively. These visual cues indicate which metals are the most important for characterizing each PC.

PC1 has lead, zinc, copper, and cadmium loading negatively, and beryllium, magnesium, chromium, cobalt, nickel, vanadium, potassium, and aluminum loading positively. This suggests that samples that have negative scores on PC1 have proportionally higher concentrations of lead, zinc, copper, and cadmium compared to the other metals. This does not necessarily imply that samples with more negative PC1 scores have higher absolute concentrations of these metals, but that they had higher relative concentrations (relative to other metals in the sample).

PC2 has negative loadings of mercury and cadmium, and positive loadings of cobalt, sodium, copper, manganese, and iron. PC3 has negative loadings of calcium, and no positively loading metals above 0.5.

2.3.1.2 BIPLOTS

Plotting PC1 versus PC2 shows a distinctive horseshoe shape (Figure C-3). This is a well-known phenomenon in ecological studies (e.g., Goodall 1954; Podani and Miklós 2002), and suggests that there is a confounding variable with a strong gradient relative to the covariance in the metals data. Gradients can be in time, space, soil composition, sediment grain size, or could be a linear combination of any of the former variables, or other unmeasured variables. Practically, this means that the first PC axis (PC1) cannot be used by itself to separate samples, but that at least the first two dimensions need to be considered together.

The biplot for PC1 versus PC2 (Figure C-3) shows samples plotting in the upper left that have relatively higher proportions of zinc, copper, and barium compared to other samples. Those samples in the lower left quadrant also have higher relative proportions of mercury and cadmium.

2.3.2 CLUSTER RESULTS

Results for the cluster analysis are described below.

2.3.2.1 SELECTION OF CLUSTER NUMBER

Hierarchical cluster analysis with Euclidean distance and Ward linkage was applied to the first three PCs (scaled to mean of zero and unit variance). The top three proposed number of clusters were three clusters with 14 out of 22 cluster fit metrics, six proposed clusters with three metrics, and two proposed clusters with two metrics. Therefore, the three cluster solution was carried forward as the optimal solution (Table C-2).

2.3.2.2 DESCRIPTION OF THE CLUSTER RESULTS

The three clusters were numbered based on their position in the PC1 versus PC2 biplot, beginning with Cluster 1 in the upper left quadrant and ending with Cluster 3 on the far right (Figure C-4). The following describes cluster characteristics based on their positions in the biplots:

- **Cluster 1** (green; n = 345) has higher relative proportions of zinc, lead, copper, and cadmium (negative PC1) and higher relative proportions of iron, manganese, and copper (positive PC2) with lower relative proportions of mercury and cadmium compared to other samples.
- **Cluster 2** (orange; n = 559) has higher relative proportions of zinc, lead, copper, and cadmium (negative PC1) and higher relative proportions of cadmium and mercury (negative PC2) compared to other samples.
- **Cluster 3** (purple; n = 737) has relatively higher proportions of beryllium, magnesium, chromium, cobalt, nickel, vanadium, potassium, and aluminum (positive PC1), while not having any particularly higher or lower relative concentrations of zinc and copper versus cadmium and mercury (0 centered PC2). The samples in this cluster were selected to represent background metal conditions in OUs 1 and 2, and these samples were used to calculate BTVs.

Additional characteristics of each cluster are presented in Figures C-5 through C-8. Figure C-5 presents boxplots of metal concentrations by cluster. As can be seen in the boxplots, most metals have higher concentrations in Cluster 1 (only exceptions are cadmium, magnesium, mercury, and nickel), and the remaining metals have higher concentrations in Cluster 2 (e.g., cadmium and mercury). For all metals, Cluster 3 has the lowest concentrations.

The spatial distribution of cluster results was evaluated using area categories. Samples were categorized by area as follows and shown in Map C-3a through Map C-3l:

- OU 1 North CSM Unit
- OU 1 South CSM Unit
- Transitional CSM Unit (OU 2)
- Upper Lacustrine CSM Unit (OU 2)
- Middle Lacustrine CSM Unit (OU 2)
- Lower Lacustrine CSM Unit (OU 2)
- Mainstem Columbia River in British Columbia below Trail
- Mainstem Columbia River in British Columbia above Trail, including Lower Arrow Lake
- Tributaries of the UCR in the U.S.
- Tributaries of the Columbia River in British Columbia, Canada

Figure C-6 and Table C-3 show the cluster composition for each of the spatial areas evaluated, while Table C-4 presents the assigned cluster for all individual samples. Samples from Cluster 1 are primarily located in OU 1 North, with some also found in OU 1 South, the Transitional CSM Unit (OU 2), and the Lower Columbia River in British Columbia below Trail. Aside from one sample assigned to Cluster 1 in the Upper Lacustrine CSM Unit[9], no other Cluster 1 samples are found farther downstream of this unit. Cluster 2 samples are distributed across all areas except for the mainstem Columbia River in British Columbia above Trail. The highest percentages of Cluster 2

[9] The only sediment sample in OU 2 downriver of the Transitional CSM Unit assigned to Cluster 1 was from a subsurface sediment core collected during the 2005 Phase 1 Sediment Sampling at River Mile 692 (Location ID RM692C1). This sediment sample was collected from a depth of 36 to 60 inches below the sediment bed surface.

samples are found in OU 1 South and the Lower Columbia River in British Columbia below Trail. Cluster 3 samples are present in all areas except the Lower Columbia River in British Columbia below Trail, with the highest percentages found in U.S. and Canada tributaries, the mainstem Columbia River in British Columbia above Trail, and CSM units in OU 2. Notably, Cluster 3 has the lowest percentage of samples in OU 1 North and OU 1 South.

Clusters were also evaluated with respect to the grain size composition of the associated samples, when available. Sediment grain size analytical results for samples were summed across size fractions to create three standardized grain size categories: fines, sand, and gravel. This standardization of grain size can, in some cases, result in grain size sums in excess of 100 percent. In general, this is the result of laboratory methods and/or rounding. Thus, as an additional step, grain size was normalized to 100 percent prior to its use. Fine sediments (or fines) were defined as grain sizes less than or equal to 0.074 millimeters (mm) (for 2005 Phase 1 Sediment Sampling [USEPA 2006b], 2013 Phase 2 Sediment Study [TAI 2017], and 2019 Phase 3 Sediment Study samples [TAI 2022]) or less than or equal to 0.0625 mm (for 2009–2011 Beach Sediment Study [TAI 2014] and 2015 Bossburg Flat Sediment and Soil Study [TAI 2016] samples), and they include size fractions representing silts, clays, and colloids. For this background analysis, sand was defined as grain sizes between 0.074 mm or 0.0625 mm and 2 mm, and gravel was defined as grain sizes between 2 mm and 64 mm.

Figure C-7 presents boxplots of percent sand, fines, and gravel by cluster designation. Samples in Clusters 1 and 3 are generally sandy, with 50 percent of samples in each cluster having greater than 70 percent sand. Samples in Cluster 2 generally contain higher percent fines. Samples in Cluster 3—the cluster selected for developing BTVs—are representative of sandy sediment and do not capture the full range of finer-grained sediments (fines) present at the Site, particularly within OU 2. Figure C-8 illustrates the percent fines for all samples used in this analysis, with Cluster 3 samples highlighted. As shown in the figure, the majority of Cluster 3 samples contain less than 50 percent fines.

2.3.2.3 VALIDATION AND RELIABILITY OF CLUSTER GROUPINGS

Multiple lines of evidence were used to validate the findings of the cluster analysis and assess validity. The spatial distribution of clusters (Figure C-6) showed that Cluster 3 (the background cluster) is the only cluster identified for samples from the Columbia River north of Trail, and was also prevalent for tributary samples. Boxplots showing the distribution of metals concentrations in each cluster provided important internal validity for the statistical results (Figure C-5), with the clusters separating based on different concentrations of key metals. The background cluster (Cluster 3) was the lowest in metals concentrations, consistent with sediment that has been unimpacted by specific point sources.

In addition to validating the statistical results, cluster reliability and sample fidelity was also assessed. As described previously, a bootstrapping procedure was used to assess the likelihood of samples changing cluster membership. The cluster reliability assessment was reported as the percentage of samples that change cluster assignments between the original cluster group and the bootstrapped cluster groups. For example, a cluster that has 95 percent cluster reliability has 5 percent of its samples assigned to different clusters across the 1,000 bootstrap replicates.

The cluster reliability assessment showed high reliability for two of the three clusters (Table C-5). Cluster 3 showed the highest reliability with 97.9 percent of samples in the original Cluster 3 being assigned to the same cluster across the bootstrap sampled replicates; most importantly, no samples from Cluster 3 were ever found to be assigned to Cluster 1. Cluster 1 showed 86.0 percent reliability, with 13.8 percent of samples ending in Cluster 2. Reinforcing the Cluster 3 findings indicated previously, an extremely small percentage (0.3 percent) of Cluster 1 samples ended in Cluster 3. Cluster 2 had the lowest reliability at 78.4 percent. For Cluster 2, 20.2 percent of the misclassified samples ended up in Cluster 3, with 1.5 percent of samples ending in Cluster 1.

Individual sample fidelity results for Cluster 3 are presented in Table C-6. Of the 737 total samples in this cluster, 68 samples exhibited fidelity below 95 percent, meaning they had less than a 95 percent probability of being reassigned to Cluster 3 during bootstrapping. The remaining 669 samples demonstrated fidelity greater than 95 percent and are therefore considered stable. Based on this analysis, to calculate the BTV, those Cluster 3 samples with less than 95 percent fidelity were removed, and only those samples that had greater than 95 percent fidelity (n=669) were used in the calculation.

2.4 SEDIMENT BACKGROUND THRESHOLD VALUES AND BACKGROUND THRESHOLD VALUES HAZARD QUOTIENTS

Sediment BTVs, calculated as described in Section 2.2.2 of this appendix using samples classified as Cluster 3 with high-fidelity, are presented in Table C-7. BTVs were calculated for antimony, selenium, silver, and thallium from samples containing these metals in Cluster 3, although they were not used in the PCA and cluster analyses (Attachment C2). There were fewer than 10 samples from Cluster 3 that included results for molybdenum; therefore, no BTV was calculated for molybdenum.

To assess the impact of including samples from OU 1 in the BTV calculations, BTVs calculated from the full background cluster compared to BTVs where samples from OU 1 are excluded are presented in Table C-8. As can be seen, the inclusion of the 58 samples from OU 1 that fall within the background cluster have a minimal impact on the calculated BTVs. For most metals, there was a less than 1 percent difference, and all metals show less than a 7 percent change in BTVs, with the exception of mercury (which changes 0.01 mg/kg). Therefore, it was concluded that inclusion of the Cluster 3 samples from OU 1 in the BTV calculations has a minimal impact on the BTVs.

For the Aquatic BERA, BTV HQs are calculated to provide context for the UCR Site HQs calculated in the BERA. BTV HQs are calculated using the same approach as the Site HQs (see Section 4 of Volume 1), but using the sediment BTVs presented in Table C-7 as the exposure point concentration. BTV HQs using the sediment BTV are calculated for the following exposure pathways and receptor groups: direct contact to sediment for aquatic plants and benthic invertebrates, and dietary dose for fish, birds, and mammals. For dietary dose, BTV HQs are calculated only for receptors for which all components of their diet are modeled from sediment concentrations. Bioaccumulation of chemicals of potential concern (COPCs) from sediment is modeled for aquatic plants, small aquatic invertebrates, and adult flying aquatic emergent insects, whereas COPC concentrations for fish, crayfish, and mussels are estimated from sampled biota

tissue concentrations (see Section 4.1.2.3 of Volume 1). Therefore, dietary dose BTV HQs are calculated for all receptors that eat only aquatic plants, small aquatic invertebrates, and/or adult flying aquatic emergent insects; this includes largescale sucker, longnose dace, tundra swan, spotted sandpiper, mallard, tree swallow, muskrat, water shrew, and little brown bat (see Section 4.1.2.1 and Table 4-3 of Volume 1).

The BTV HQs using the sediment BTV are presented in Aquatic BERA Appendix M alongside the calculation of Site HQs.

2.5 COMPARISON OF SEDIMENT BACKGROUND THRESHOLD VALUES TO OTHER REGIONAL BACKGROUND DATA SETS AND FOR THE COLUMBIA RIVER NORTH OF TRAIL

Previous studies have included assessments of regional background (or reference) sediment metals concentrations that were either used or intended to be used for comparing to sediment metals concentrations at the UCR Site. This section provides a summary of other regional background data sets and a comparison of the sediment BTVs to background concentrations developed from these other available regional background data sets. This section also provides alternative BTVs developed from only Cluster 3 samples that are in the mainstem Columbia River in British Columbia north of Trail. The comparisons serve to contextualize the sediment BTVs and assess their representativeness to regional background sediment concentrations and illustrate the variability in estimates of background concentrations.

Studies with applicable regional background or reference sediment metals concentrations include the following:

- 2010 Vlassopoulos Expert Report (Vlassopoulos 2010)
- Regional Background Concentration Technical Memorandum (MacDonald 2014)
- 2004 USGS Toxicity Evaluation (Besser et. al 2007)
- 2002–2003 USGS Sediment Core Sampling (USGS 2005)
- 2001 USGS Beach and Bed Sediments of Lake Roosevelt (USGS 2003)
- 2001 Reassessment of Toxicity of Lake Roosevelt Sediments (Ecology 2001)
- Assessment of Columbia River Receiving Waters (Teck Cominco Ltd. 2001)
- 1992 USGS Sediment Quality Assessment (USGS 2001)
- 1986 Ecology Assessment of Metals (Ecology 1989)

Regional background data sets were compiled from each study and are presented in Table C-9. Most of the studies summarized in Table C-9 relied on samples collected from the mainstem Columbia River in British Columbia above Trail to describe background or reference metals concentrations. These include USGS (2003), Teck Cominco Ltd. (2001), Ecology (2001), USGS (2001), and Ecology (1989). Studies by USGS (2007) and MacDonald (2014) relied on sediment samples collected in tributaries to the UCR to develop background or reference concentrations, and USGS (2003) collected samples of glacial sediments collected above the current Lake Roosevelt water level. Vlassopoulos (2010) presented concentrations of "pre-smelter" sediment obtained from a series of cores collected in OU 1 North. Other investigations that included

collection of sediment cores at the Site in 2002 to 2003 (USGS 2005) and 2005 (USEPA 2006b) did not identify specific samples intervals as representing background or reference sediment conditions; therefore, results from core samples from the Phase 1 Sediment Sampling (USEPA 2006b) and the 2002–2003 USGS Sediment Core Sampling (USGS 2005) are not included in Table C-9.

As noted above, these studies encompass a broad geographic and temporal range for estimating regional background sediment conditions. Many of these studies employ different sampling strategies, sample sizes, locations, analytical methodologies, and statistical approaches to develop background values which make it inappropriate to directly compare concentrations among these studies.

3. SOIL BACKGROUND

Soil BTVs were used in the evaluation of the RFDAs and the WSDAs in Volume 4 of the Aquatic BERA. The final soil BTVs were approved by EPA in 2020 (Attachment C1). The soil BTVs used in Volume 4 are presented in Table C-10 as well as in Aquatic BERA Volume 4. The final technical memorandum presenting the approach and soil BTVs are presented as Attachment C1 of this appendix.

For calculating BTV HQs using the soil BTV, the same approach as the sediment BTV HQs (see Section 2.4 above) is used. Dietary dose BTV HQs can be calculated for all evaluated terrestrial receptors, as COPC concentrations in terrestrial food items are modeled from soil concentrations (see Section 4.1 of Volume 4). The BTV HQs using the soil BTV are presented in Aquatic BERA Appendix M.

4. POREWATER BACKGROUND

This section describes the development of the BTVs for porewater, including the data set preparation and the calculation of the BTVs.

4.1 POREWATER BACKGROUND DATA SET

As described in the Data Usability Assessment (DUA) for the Aquatic BERA (Appendix A), the Aquatic BERA data set includes field-collected porewater data from three studies in the UCR: the 2013 Phase 2 Sediment Study (TAI 2017), the 2015 USGS Porewater Study (USGS 2016), and the 2019 Phase 3 Sediment Study (TAI 2022). The Phase 2 field porewater data were collected from locations in OU 1 and OU 2 while field porewater samples from the 2015 USGS and 2019 Phase 3 studies were collected solely from OU 1. The Phase 2 and Phase 3 studies also included collection of field porewater samples from locations in the Columbia River, upstream of Trail, British Columbia. No upstream reference locations were sampled in the 2015 USGS Porewater Study.

In the 2013 Phase 2 Sediment Study, upstream reference samples were collected from two locations in the riverine reach near Genelle and from two locations in Lower Arrow Lake (TAI 2017) (Map C-4). Samples were collected by extracting water out of the sediment grab sampler at the time of collection. In cases where water could not be removed from the grab sampler, the sediment sample was transferred to a mixing container and the porewater sample was collected by siphoning out the water from the mixing container with the assumption that it represented porewater when it was in situ (see Appendix A for more detail regarding the collection of porewater during Phase 2).

In the 2019 Phase 3 Sediment Study, upstream reference samples were collected from 12 locations in the riverine reach upstream of Trail and from 6 locations from Lower Arrow Lake (Map C-4). Four riverine reference samples were collected from the Birchbank area and eight were collected from the reach near Genelle (TAI 2022). The porewater samples from the Phase 3 sediment study were collected in situ using a Trident probe prior to the collection of sediment samples.

4.2 APPROACH TO CALCULATING POREWATER BACKGROUND THRESHOLD VALUES AND BACKGROUND THRESHOLD VALUES HAZARD QUOTIENTS

BTVs are calculated on the concentrations of dissolved metals in porewater from the background data set to help understand the nature and extent of COPC concentrations in OUs 1 and 2 relative to upstream reference conditions. Additionally, porewater BTV HQs are calculated to provide a basis for comparison of risks from the Site to background risks under upstream reference conditions.

Due to uncertainties associated with the porewater data, the porewater concentration BTVs and the porewater BTV HQs are calculated for multiple data handling scenarios as described in detail below. ProUCL input and output files associated with each of the below scenarios for the porewater BTVs are presented in Attachment C3.

4.2.1 UNCERTAINTIES ASSOCIATED WITH U* QUALIFIED POREWATER DATA

As noted in the Phase 2 Data Summary Report (TAI 2017) and the Phase 3 Data Summary Report (TAI 2022), some of the porewater results from the upstream reference areas were assigned U* qualifiers and are thus considered nondetected results for use in this BERA. The results were reported as detected by the analytical laboratory but were subsequently qualified as nondetected by the data validator based on the detected concentrations of metals in the associated equipment blank(s). The U* flag was applied to indicate uncertainty in the reported result due to the detection of the analyte within a factor of 5 in an associated blank quality control sample, including equipment rinsate, laboratory, or filtration blank samples. Most U* qualifiers were assigned based on detections in the associated equipment rinsate blank collected in the field at the time of porewater sampling. The reported results for those samples are used to represent the concentrations for the U* qualified results consistent with the handling of nondetected values in the Aquatic BERA. However, because there is uncertainty as to whether equipment contamination caused reference sample concentrations to be inflated and, by extension, any BTVs calculated based on those results, additional analyses were conducted to attempt to bound the potential uncertainty of the BTVs calculated from the upstream porewater data.

The analyses to address uncertainties from blank contamination included a series of scenarios where equipment rinsate blank concentrations were subtracted from the reported analytical results for U* samples. The blank-subtraction approach was only applied to the Phase 3 porewater data because none of the toxicity modifying factors that are input parameters into the biotic ligand model (e.g., dissolved organic carbon, alkalinity) were U* qualified (TAI 2022). In the Phase 2 study, several of the toxicity modifying factors required for calculation of benchmark values were detected in the porewater equipment blank sample which resulted in U* flags on many of the results for toxicity modifying factors in the Phase 2 data set. Applying the blank-subtraction approach to those parameters resulted in unrealistic porewater chemistry values leading to significant uncertainty in estimates of bioavailability. Therefore, the Phase 2 data were not included in the blank-subtraction analyses.

The blank-subtraction approach for adjusting reported results and subsequent calculation of BTVs and BTV HQs involved the steps listed below. Blank subtractions were only evaluated for the porewater COPCs aluminum, antimony, cadmium, copper, iron, lead, manganese, and zinc.[10] The stepwise procedure is as follows:

1. For analytes with U* flagged results, the reported concentration in the associated equipment blank sample is subtracted from the reported concentration in the field-collected sample. In samples where the reported concentration was less than the reported concentration in the corresponding equipment blank sample, sample results were set to the detection limit. For the Phase 3 data set, one equipment rinsate blank was collected that corresponded to all reference area samples (TAI 2022). The reported results from the relevant equipment blank are provided in Table C-11.

[10] The blank subtraction evaluation was not performed for molybdenum, a porewater COPC, because porewater samples were not analyzed for molybdenum in the 2019 Phase 3 Sediment Study (TAI 2022).

2. The blank-subtracted metals concentrations are used to calculate blank-adjusted BTVs of dissolved metals concentrations.
3. For analytes with sample-specific benchmarks (cadmium, copper, lead, and zinc), the blank-subtracted metals concentration from each sample is used to calculate a blank-subtracted HQ.
4. The blank-subtracted HQs from the reference data set are used to calculated blank-subtracted BTV HQs.

4.2.2 UNCERTAINTIES ASSOCIATED WITH OUTLIER VALUES

Among the upstream reference area porewater data, there are individual samples with porewater concentrations that are substantially higher than the remaining reference area data set. The reason for this is not known, and this therefore represents an uncertainty in the calculated BTVs. Consistent with USEPA (2002b) guidance, the potential outlier samples are identified in the data set, outlier tests are conducted in ProUCL (version 5.2, USEPA 2022) to determine whether the samples are statistical outliers, and the BTV calculations are conducted with and without the statistical outliers included to document the sensitivity of the BTV to the high-leverage data point. Output from the outlier tests as well as data tables identifying the outliers in the various BTV data handling scenarios discussed below are provided as Attachment C3 to this appendix.

4.2.3 DATA HANDLING SCENARIOS

BTVs and BTV HQs were calculated based on the following data set and data handling scenarios to address the uncertainty in the upstream porewater data set:

A. Combined Phase 2 and Phase 3 upstream reference area data set with all values as reported by the analytical laboratory, consistent with how data were handled throughout this BERA. Specifically, the concentrations reported by the laboratory were used for U* qualified results.

B. Combined Phase 2 and Phase 3 upstream reference area data set with statistical outlier values removed to document the sensitivity of the BTV to the high-leverage data point. Scenarios A and B, because they are based on the combined porewater data set and reported values, are most analogous to the handling of the porewater data set in the Aquatic BERA.

C. The Phase 3 upstream data set with all values as reported by the analytical laboratory. This scenario was included for comparison with scenarios E and F below.

D. The Phase 3 upstream data set with statistical outlier values removed. This scenario was included for comparison with scenarios E and F below.

E. The Phase 3 upstream data set after the concentrations of detected values in rinsate blanks have been subtracted from the reported results based on the approach described in Section 4.2.1 above. As discussed in that section, the blank-subtraction approach was only applied to the Phase 3 porewater data because of the additional uncertainty in the Phase 2 from U* qualification of toxicity modifying factors in addition to the dissolved metals concentration in porewater.

F. The Phase 3 upstream data set after the concentrations of detected values in rinsate blanks have been subtracted from the reported results and the remaining statistical outliers have been removed.

4.3 POREWATER BACKGROUND THRESHOLD VALUES AND BACKGROUND THRESHOLD VALUES HAZARD QUOTIENTS

Porewater BTVs and BTV HQs were calculated for each COPC for each of the data handling scenarios listed above. BTVs and BTV HQs from each of the data set scenarios listed above were calculated in ProUCL (version 5.2, USEPA 2022) consistent with the approach for sediment BTVs described above in Section 2.4[11]. Porewater BTVs for COPCs were calculated using the dissolved concentrations of each COPC from the upstream reference areas based on each of the data handling scenarios. The approach for calculating porewater BTV HQs, however, differed depending on the relevant benchmark:

- For porewater benchmarks that are static values (e.g., ambient water quality criteria for antimony, iron, and molybdenum, as well as some taxa-specific benchmarks; see Appendix F of this BERA), porewater BTV HQs were calculated by dividing the porewater BTV for the dissolved metal by the porewater benchmark.
- For porewater benchmarks that are functions of location-specific data (e.g., pH, dissolved organic carbon, and hardness) (Appendix F of this BERA), BTV HQs were calculated as follows:
  - Toxic units were calculated for each reference location sample using the sample-specific data.
- The porewater BTV HQ was calculated in ProUCL based on the distribution of HQs from the reference data set using the same statistical approach described in Section 2.4.

Because the UTLs calculated in ProUCL sometimes exceeded the maximum reported result in the reference data set, both the data set maximum and calculated UTL are reported in Table C-11. However, the minimum of those two values was selected as the BTV for that data scenario.

Of the various data set scenarios evaluated above, the calculated BTVs are most sensitive to the handling of statistical outliers. For example, removal of the outlier from the Phase 3 data set decreased the BTV HQ for porewater copper (based on the aquatic life benchmark) by more than 50 percent (from 7.4 to 3.4) while applying the blank-subtraction approach decreased the BTV HQ by approximately 20 percent (from 7.4 to 6.0).

To reflect the uncertainty in the reference area porewater data set, the BTVs and BTV HQs for each COPC are expressed as ranges based on the data set scenarios A through F summarized above. In the Aquatic BERA, the calculated exposures and risks to benthic invertebrates and fish from exposure to porewater are compared to the range of BTV HQs presented in Table C-12.

[11] The ProUCL output files from the BTV analyses are provided as Attachment C3 to this appendix.

Vlassopoulos, D. 2010. Expert Report of Dimitrios Vlassopoulos, Pakootas, et al. v. Teck Cominco Metals Ltd., Case No. CV-04-0256-LRS United States District Court for the Eastern District of Washington. September 17, 2010.

TABLES

Table C-1
Data Sets Used in the Sediment Background Analysis
Upper Columbia River
Final Aquatic Baseline Ecological Risk Assessment
Appendix C

Data Set	Number of Sediment Samples Used in Background Analysis	Reference
2001 EPA Stevens County Mines and Mills	9	USEPA (2002a)
2001 Expanded Site Investigation	163	USEPA (2003)
2005 Phase 1 Sediment Sampling	362	USEPA (2006a)
2009–2011 Beach Sediment Study	640 [a]	TAI (2014)
2010 White Sturgeon Sediment Toxicity Study	6	TAI (2018)
2015 Bossburg Flat Sediment and Soil Study	99 [a]	TAI (2016)
2013 Phase 2 Sediment Study	136	TAI (2017)
2019 Northport Waterfront RI [b]	63	Ecology (2019a)
2019 Phase 3 Sediment Study	105	TAI (2022)
2012–2013 AREMP Teck Trail Operations	10	Teck Metals Ltd. (2014)
2001 Trail Area Stream Sediment Background	28	Reyes et al. (2004)
2015–2016 AREMP Teck Trail Operations	10	Teck Metals Ltd. (2017)
2018 AEMP Teck Trail Operations	10	Teck Metals Ltd. (2019)
USGS: Bortleson et al. Sediment Quality Assessment 1992	0 (Incomplete metals analyte list)	USGS (2001)
Ecology: Johnson et al. Assessment of Metals Contamination in Lake Roosevelt 1986	0 (Incomplete metals analyte list)	Ecology (1989)
USGS Reformatted NURE HSSR Program	0 (Incomplete metals analyte list)	USGS (2007)
2001 Reassessment of Toxicity of Lake Roosevelt Sediments	0 (Incomplete metals analyte list)	Ecology (2001)
2007 Ecology Reconnaissance and Sediment Sampling	0 (Incomplete metals analyte list)	Ecology (2007)
Teck Golder 2007 Sediment Triad Report	0 (Incomplete metals analyte list)	Teck Metals Ltd. (2007)
2002–2003 USGS Sediment Core Sampling	0 (Total digestion preparation method)	USGS (2005)
USGS Midnite Mine Sediment Study	0 (Incomplete metals analyte list, sample preparation method [c])	USGS (2008)

Notes:
Full references presented in appendix main text.

[a] Excludes samples specifically collected for human health risk assessments, which were performed on the less than 250 micrometers (µm) sieve fraction.

[b] Samples comprise sediment locations as well as 14 soil locations below the estimated pre-1973 maximum river flood level, which are included due to their potential for seasonal inundation by the Columbia River and potential for slag deposition.

[c] Samples were sieved to < 150 µm at the time of collection.

AEMP = Aquatic Effects Monitoring Program
AREMP = Aquatic Receiving Environment Monitoring Program
ESI = expanded site inspection
HSSR = Hydrogeochemical and Stream Sediment Reconnaissance
NURE = National Uranium Resource Evaluation
PA/SI = preliminary assessment and site inspection
RI = remedial investigation
USGS = U.S. Geological Survey

Notes:
Full references presented in appendix main text.
[a] Concentrations of trace elements in core sediments collected for this study were compared to reported concentration of trace elements in reference sediments that were collected from bank material adjacent to the reservoir (USGS 2003) and river sediment collected upstream of the smelter (USGS 2001).
[b] Glacial sediments above the high-water elevation along the upper banks of Lake Roosevelt were collected at three locations (River Mile [RM] 690, RM 670, and RM 635). These were collected as subsurface composites, where an exposed bank above the high water line was selected, and at least the top 15 centimeters of material was removed before the sample was taken. Beach- and bank-sediment samples were also collected from two locations on Lower Arrow Lake in British Columbia.
BTV = background
CCT = Confederated
LCR = Lower Columbia
mg/kg-dw = milligram(s) per kilogram-dry weight
NR = not reported
TRM = total recoverable metals
UTL = upper tolerance limit

Table C-10

Thallium	0.56	NA	0.56
Vanadium	47.5	NA	47.5
Zinc	111	NA	111

Notes:

For each metal, the selected background threshold value (BTV) represents the most conservative value (i.e., lowest BTV), within that analytical preparation method group.

[a] BTVs calculated with and without outliers are indicated with a forward slash (for example 13 / 12), respectively.

[b] Samples identified for exclusion by EPA based on multivariate analyses and location (Attachment C1 of Appendix C).

[c] BTVs were developed by TAI and approved by EPA (Attachment C1 of Appendix C). Values for metals other than mercury are the partial digestion BTVs.

COI = chemical of interest

COPC = chemical of potential concern

mg/kg = milligram(s) per kilogram(s)

NA = not applicable

Notes:
Bolded values indicate the chosen statistic to represent the background threshold value (BTV) for each version of the data set. The lower of the two values between the upper tolerance limit (UTL) and the maximum is the statistic chosen.
Approach letters (e.g., Approach A, Approach B) correspond with the descriptions of each approach method as presented in Section 2.2 of Appendix C.
All UTLs calculated using ProUCL, Version 5.2.
[a] The range of BTV values shown represents the range of the chosen statistic (bolded values) for each approach scenario.
µg/L = micrograms per liter
AWQC = ambient water quality criteria
NC = not calculated
TU = toxic unit (calculated as the sample concentration / benchmark; depending on the analyte, the benchmark may be adjusted for toxicity using sample-specific measurements such as pH and organic carbon content)

Subject: *Revised Draft Final Technical Memorandum - Assessment of Background Concentrations of Metals and Metalloids in Upland Soils*, dated June 29, 2020

Dear Kris,

EPA has reviewed and approves the Draft Final Technical Memorandum – Assessment of Background Concentration of Metals and Metalloids in Upland Soils (6/29/2020). EPA appreciates Teck American Incorporated's (TAI) additional effort to revise the document in accordance with EPA's May 29, 2020 letter and analysis, and we look forward to receiving the final document.

This letter includes two attachments; Attachment 1 provides brief responses to TAI's July 7, 2020 letter, and Attachment 2 is an updated table that includes EPA's response to TAI's July 7, 2020 comments.

Please let me know if you have any questions or concerns.

Sincerely,

Kathryn S. Cerise

Subject: Upper Columbia River Remedial Investigation and Feasibility Study – Final Technical Memorandum – Assessment of Background Concentrations of Metals and Metalloids in Upland Soils (July 2020)

Dear Kathy:

On behalf of Teck American Incorporated (TAI) and further to the U.S. Environmental Protection Agency's (EPA's) approval email dated July 15, 2020, I am pleased to submit the above-referenced final technical memorandum. We wish to confirm that this final memorandum is available to download on the Upper Columbia River Remedial Investigation and Feasibility Study website (www.ucr-rifs.com).

Sincerely,
Teck American Incorporated

Denise Mills, LHG
Program Manager, Upper Columbia River

TECHNICAL MEMORANDUM — FINAL

TO:	Kris McCaig, Manager, Environmental and Public Affairs, and Denise Mills, Program Manager, Upper Columbia River, Teck American Incorporated
FROM:	Exponent and ERM West, Inc.
DATE:	July 21, 2020
PROJECT:	Upper Columbia River RI/FS
SUBJECT:	Assessment of background concentrations of metals and metalloids in upland soils

1 Introduction

This memorandum presents the revised results of the upland soils natural background assessment and an exploratory evaluation of area background performed for the Upper Columbia River (UCR) Site (hereafter the Site[1]). The results present background threshold values (BTVs) for metals and metalloids[2] that estimate natural background in and around the Site. The background assessment was conducted according to the U.S. Environmental Protection Agency (EPA)-approved data quality objectives (DQOs) (TAI 2018b; USEPA 2018) based in part on EPA's level of effort (LOE) memorandum regarding the assessment and estimation of background elemental concentrations in upland soils from the UCR (USEPA 2016a). In addition, this technical memorandum incorporates comments by EPA related to previous versions of this assessment (USEPA 2019, 2020a,b,c). The results will be used to inform the UCR remedial investigation and feasibility study (RI/FS) and baseline ecological risk assessment (BERA) being conducted by Teck American Incorporated (TAI), and

[1] The UCR Site as defined within the June 2, 2006 Settlement Agreement (USEPA 2006a) is the areal extent of hazardous substances contamination within the United States in or adjacent to the Upper Columbia River, including the Franklin D. Roosevelt Lake, from the U.S.-Canada border to the Grand Coulee Dam, and those areas in proximity to the contamination that are suitable and necessary for implementation of response actions.

[2] The metals and metalloids assessed will include those listed in Table 2-1 of the Upper Columbia River Soil Study (TAI 2015b), which are aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, molybdenum, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc. Thus, in this document "metals and metalloids" refers only to this list of elements. These metals and metalloids were identified as chemicals of interest for the referenced soil study and were considered in the assessment of natural background soil concentrations.

the site-wide human health risk assessment (HHRA) being conducted by EPA (USEPA 2006a, 2016b).

The natural background assessment screened a large dataset from multiples sources (see Section 2.3.1 for details). After exclusionary criteria were applied, the data were assessed for consistent and representative soil measurements comparable to the soil data developed for use in the RI/FS. The background dataset that was initially developed following the data screening and selection criteria in the EPA-approved final DQOs included samples collected from 23 locations for the UCR Upland Soil Study (TAI 2015b). This dataset was deemed insufficient in size and geographic distribution to characterize background soil conditions in the study area. Thus, at EPA's request, the exclusionary criteria were relaxed to increase the number of samples included and the geographical coverage (USEPA 2019). This included merging results into one dataset regardless of the method of sample preparation and analysis. Subsequently, EPA requested that results be segregated by method for comparability to like results (USEPA 2020a,b). In comments provided to TAI on May 29, 2020, EPA required certain additional results be excluded from the BTV dataset based on multivariate analyses provided with their comments (USEPA 2020c). These deviations from the DQOs are described in the following sections.

An exploratory assessment of area background (e.g., an evaluation of anthropogenic influences on soil chemistry not related to the smelter in Trail, BC) was also conducted. Some of the exclusion criteria that were applied to the background dataset for estimation of natural background were designed to eliminate samples associated with anthropogenic activities and features and therefore, resulted in screening out data useful for the area background assessment. Metal and metalloid data plus added location-based information about anthropogenic sources were used to derive the exploratory area background dataset.

Figures and tables are included after the main text unless presented as an insert.

2 Natural Background Assessment

The primary objective of the natural background assessment was to ascertain the natural background soil concentrations as defined by Model Toxics Control Act (MTCA; Washington Administrative Code [WAC] 173-340-200[3]) and EPA (USEPA 2002a[4]). Results will be used in the RI to identify those areas where measured soil concentrations of the chemicals of potential concern (COPC) are no higher than natural background. This information will be used to provide context in the BERA and HHRA.

2.1 Study Background

In 2016, EPA issued an LOE memorandum to TAI (USEPA 2016a), which outlined an approach for compiling a background dataset from preexisting data sources and included DQO Steps 1, 2, and 3 of the EPA's DQO process (USEPA 2006b). In the memorandum, EPA evaluated 13 studies considered usable for compiling a background dataset for the Site. EPA's primary criteria were that all samples should have a known location (i.e., known spatial coordinates and depth) that is near the Site and were collected in areas outside the following influences:

- The 100-year floodplain
- The 1931 "zone of sulfur dioxide injury" described by Scheffer and Hedgcock (1955; referred to herein as the "1931 SO_2 plume area")
- Areas disturbed by human activity

[3] WAC 173-340-200:

"Natural background" means the concentration of hazardous substance consistently present in the environment that has not been influenced by localized human activities. For example, several metals and radionuclides naturally occur in the bedrock, sediments, and soils of Washington state due solely to the geologic processes that formed these materials and the concentration of these hazardous substances would be considered natural background. Also, low concentrations of some particularly persistent organic compounds such as polychlorinated biphenyls (PCBs) can be found in surficial soils and sediment throughout much of the state due to global distribution of these hazardous substances. These low concentrations would be considered natural background. Similarly, concentrations of various radionuclides that are present at low concentrations throughout the state due to global distribution of fallout from bomb testing and nuclear accidents would be considered natural background.

"Area background" means the concentrations of hazardous substances that are consistently present in the environment in the vicinity of a site which are the result of human activities unrelated to releases from that site.

[4] USEPA (2002a) defines background as "constituents or locations that are not influenced by the releases from a site, and is usually described as naturally occurring or anthropogenic (EPA, 1989; EPA, 1995a):

1) *Anthropogenic* – natural and human-made substances present in the environment as a result of human activities (not specifically related to the CERCLA release in question); and,

2) *Naturally occurring* – substances present in the environment in forms that have not been influenced by human activity."

- Areas affected by natural processes such as landslides that may expose lithic materials that are not representative of surficial soils.

Data that met these initial screening criteria were evaluated further by EPA with respect to sample collection methods, chemical analysis methods, and detection limits.

The DQOs for this study (TAI 2018b) expanded upon the LOE memorandum (USEPA 2016a) to compile a dataset of soil metal and metalloid concentrations in surface and near-surface soils from northeast Washington State that is of sufficient data quality to calculate summary statistics for use in the BERA and HHRA. Methods for defining natural background concentrations are provided in WAC 173-340-709, which stipulates that samples for background determination should "have the same basic characteristics as the [soil] of concern at the site."

2.2 Study Design

For this study, EPA's seven-step DQO process (USEPA 2006b) was used to determine the type, quantity, and quality of data needed to achieve study goals and establish performance and acceptance criteria for the data (TAI 2018b). EPA informed TAI on October 23, 2018, that it had no further comments on the DQO document (USEPA 2018; included in Attachment A). The DQOs (TAI 2018b) along with the associated responses to EPA's consolidated comments (RTC) (TAI 2018a) are also included in this memorandum in Attachment A.

The approach for assessing background metals concentrations described in the DQOs and implemented for this study is generally consistent with a study completed independently by the Washington State Department of Ecology (Ecology 2019) for the same area, whereby existing data were compiled, filtered, and analyzed to calculate background values. However, there are several significant differences between the Ecology (2019) study and this study. These differences include, but are not limited to, the establishment of DQOs for study planning following EPA's seven-step DQO process (USEPA 2006b) and the statistical methods used for calculating background values.

2.3 Background Dataset Assembly

As presented in the DQOs, assembly and screening of the data considered for the natural background assessment was done in three stages or "tiers," which are described below and in the flow chart shown in Figure 1.

2.3.1 Data Sources Considered

The data sources considered included the following:[5,6]

- Soils data from studies identified in EPA's LOE memorandum (USEPA 2016a)
- Studies referenced in other TAI UCR reports, as well as studies prepared for Teck Metals' Trail operations
- UCR RI/FS database
- Soil and sediment samples from the National Uranium Resource Evaluation (NURE)-Hydrogeochemical and Stream Sediment Reconnaissance (HSSR) dataset (Smith 2006; USGS 2004)[7,8]
- U.S. Geological Survey (USGS) databases and datasets including the National Geochemical Database (USGS 2016), the National Geochemical Survey (USGS 2008b), and the North American Soil Geochemical Landscapes Project (Smith et al. 2013).

2.3.2 Study Area

The study area is defined by 11 Water Resource Inventory Areas (WRIAs) (TAI 2018b). These include the following:

- WRIA 49—Okanogan
- WRIA 51—Nespelem
- WRIA 52—Sanpoil
- WRIA 53—Lower Lake Roosevelt
- WRIA 54—Lower Spokane

---

[5] As discussed in the RTC (TAI 2018a), the Canadian datasets were removed from consideration for the background assessment (see Attachment A, Specific Comment 2) primarily because the 1931 SO_2 plume area as defined by Scheffer and Hedgcock (1955), an important exclusionary criterion, is not mapped north of the U.S.-Canada border.

[6] Although the DQOs specified that data retrieved from the Ecology Environmental Information Management System (EIM) would be considered, these data are not included in this revised analysis over concerns by EPA (2019) that the data may lack the appropriate level of quality assurance for inclusion.

[7] NURE-HSSR sediments, whether from wet or dry streams, were considered as requested by EPA (2018), in addition to soil samples.

[8] The NURE-HSSR dataset includes numerous results determined by irradiated neutron activation analysis (INAA); however, only the results from Savannah River Laboratories were considered in this assessment. INAA data from Lawrence Livermore Laboratory were not included because previous work by Church (2010) concluded that the results for arsenic, cadmium, copper, mercury, lead, and zinc were not usable for background concentration determinations.

- WRIA 55—Little Spokane
- WRIA 58—Middle Lake Roosevelt
- WRIA 59—Colville
- WRIA 60—Kettle
- WRIA 61—Upper Lake Roosevelt
- WRIA 62—Pend Oreille

It is important to recognize that WRIAs are administrative areas designated by Ecology for the management of water resources and are based on watershed and drainage characteristics. Their boundaries do not consider the physical, chemical, geological, and other characteristics necessary to evaluate upland soil background conditions. A "landscape" approach that takes into consideration multiple geomorphological and geochemical factors present in the UCR area will be appropriate for future geographic stratification of the BTVs for use in the RI/FS.

2.3.3 Elements Considered

As discussed in the DQOs (TAI 2018b), this study includes the metals and metalloids[2,9] that were agreed upon by TAI and EPA as those that would be quantified in the Upland Soil Sampling Quality Assurance Project Plan (TAI 2014) for risk determination. Potassium, magnesium, calcium, and sodium were initially retained for this analysis because cation exchange capacity (CEC) may be estimated using these elements and soil pH (TAI 2018a,b). However, these elements in the datasets reviewed for this study were analyzed by methods that are not appropriate for CEC calculation because either the digestion procedures involved strong acids or the samples were analyzed for the total-element composition of the sample (e.g., irradiated neutron activation analysis; INAA). Thus, potassium, magnesium, calcium, and sodium are not included in the BTV calculations.

2.3.4 The Tier I Dataset

Using the data sources listed above, the Tier I dataset includes soil and NURE-HSSR soil and sediment samples collected from the designated WRIAs at depths of 24 in. or less with results for any of the metals and metalloids.[10] Table 1 includes a list of the studies that make up the Tier I dataset. The table also contains the number of sample locations and the years of sample collection. These locations are shown in Figure 2.

Additional descriptive data were added to the Tier I dataset based on location as discussed in the DQOs. These included the following:

- WRIA designation (Ecology 2017)

[9] Molybdenum was inadvertently omitted from the list of metals and metalloids to be evaluated in this background assessment. It has since been added to the list provided in Section 2.3.8 and is included in the BTV calculations.

[10] For many samples, only some of the metals and metalloids were analyzed.

- Location relative to the 1931 SO_2 plume area described in Scheffer and Hedgcock (1955)
- Land use code (Ecology 2010)
- Distance to the following features
  - 100-year floodplain (FEMA 2017)
  - Nearest road (USGS 2017b)
  - Nearest railway (USGS 2017b)
  - Nearest landfill (USGS 2008a)
  - Nearest landslide (WADNR 2017)
  - Mines/mills categorized by the Mineral Resources Data System (MRDS) as producer, past producer, plant, and unknown along with the name of the feature and the associated commodity codes[11] (USGS 2005)
- NURE-HSSR contamination code referred to as "CONTAMC" in the publicly available NURE-HSSR dataset[12]
- Geologic unit (Ludington et al. 2007)
- Soil designation (map units from STATSGO; USDA 2016, 2019)
- Hydrologic units (USGS 2017a) including the name and codes (HUC6, HUC8, HUC10, HUC12), plus distances to the following:
  - Nearest drainage feature
  - Nearest upgradient mineralized area and mill located in the same drainage based on the MRDS classifications included above
  - Nearest upgradient road, railway, landfill, and landslide located in the same drainage.

The distances between samples and nearest features of interest were calculated in ArcGIS by joining sample locations with the data layers containing locations of features of interest. Each sample location was assigned a straight-line distance representing how close that location was to the nearest feature in the corresponding layer. The geospatial platform used for determining the nearest upgradient feature was ArcGIS 10.5 and its Spatial Analyst extension using the "Flow Length" function in the Hydrology module. First, a flow direction raster was created from digital elevation model (DEM) using the "Flow Direction" tool. The flow direction raster shows the direction of flow out of each cell. Second, an upstream flow length raster was created using the "Flow Length" tool, which calculates the upslope distance along the flow path, from each cell to the upstream features. Lastly, the flow length to upstream features for each sample was extracted from the upstream flow length raster based on its spatial location.

[11] MRDS locations with the following metal and metalloid commodity codes were included in the screening: antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc.

[12] https://mrdata.usgs.gov/nure/sediment/

2.3.5 The Tier II Dataset

Using the Tier I dataset plus added location-based information, the Tier II criteria described in the DQOs (TAI 2018b Table 1; provided in Attachment A) were applied to screen out samples potentially impacted by anthropogenic activity with several exceptions. At the request of EPA (2019), the screening criteria were relaxed to expand the dataset to consider samples regardless of the land use code associated with their location. Because the contamination code associated with the NURE-HSSR soil and sediment samples is somewhat similar to a land use designation (e.g., grazing, farming, mining), this screening criterion[13] was also removed. Table 1 shows the number of sample locations remaining after the Tier II screening; locations are mapped in Figure 3. Sample locations screened out and the rationale for their removal are shown in Table 2.

The samples retained for additional assessment met the following criteria and are referred to as the Tier IIA dataset in the flow chart (Figure 1):

- Outside 1931 SO_2 plume area
- Distance to the nearest
  - Road ≥50 m
  - Railway ≥50 m
  - Landfill ≥500 m
  - Mine/Mill as describe above ≥500 m
  - Landslide—Outside footprint (>0 m)
  - 100-year floodplain—Outside (>0 m)

Straight-line distances were used for the Tier II screening because the potential sources of contamination to be avoided (i.e., roads, railways, landfills, mines, and mills) all include not only surface water runoff, but also fugitive dust.

After applying the above screening criteria, replicate samples were averaged and some additional exclusions were made. The resulting dataset is referred to as the Tier IIB dataset (see Table 1):

- Multiple analyses of the same sample—A subset of the NURE-HSSR samples from the Study "NURE Seds" underwent reanalysis decades after the original collection date (Church et al. 2008 [Study "CHURC08A] and USGS 2008b [Study "geochem-fU53"][14]). In order to have one set of results per sample, the reanalysis results, with the exception of silver, were retained over

[13] The DQOs only allowed the NURE-HSSR soils and sediments with a contamination code that was either "NONE", "GRAZING", or not populated (i.e., null).

[14] Study "CHURC08A" has 44 samples and Study "geochem-fu53" has 63 samples in the Tier IIA dataset, respectively. One sample (DSOR424S01) was reanalyzed in both studies. The CHURC08A results were given priority because the concentrations were lower.

the older NURE-HSSR results from the 1970s as the former include more of the metals and metalloids of interest and the analytical techniques are well documented. The older silver results were retained because the detection limit was lower.

- Additional review of Tier IIA assessments
  - Ecology (2013b) samples in proximity to the Van Stone Mine—During review of the post-Tier IIA screening, a number of samples collected from mine waste and impacted areas made it past the MRDS screening. After reviewing the location samples near the mine against information included in Ecology (2013b; Figures 5 through 7), an additional 72 samples were removed from background based on proximity to mine waste and roads (Ecology 2013b, Study "HARTC13C" 70 samples; USEPA 2002c, Study "USEPA2001Mines/Mills" 2 samples).
  - USEPA (2002c) and Church et al. (2008) samples in proximity to other mines—The locations of samples from Studies "USEPA2001Mines/Mills" and "CHURC08A" underwent supplemental review based on elevated lead, zinc, or arsenic results for samples just beyond the 500 m setback (e.g., lead, zinc, and arsenic concentrations as high as 5,000 mg/kg, 15,000 mg/kg, and 182 mg/kg, respectively). The review indicated that although the samples were over 500 m away from the MRDS points designated for nearby mines, the samples were collected near what appear to be tailings areas. Thus, 14 samples in the proximity of the Sierra Zinc, Pend Oreille, Yellowhead, and Midnite Mines were excluded.
  - Remove replicate results for arsenic from USGS (2008b), Study "geochem-fU53". (Results by atomic adsorption spectrometry [AAS] had lower detection limits and were retained over inductively coupled plasma [ICP]-atomic emission spectrometry [AES] results.)

2.3.6 The Tier IIIA Dataset

As stated in the DQOs, additional information on samples in the Tier IIB dataset were reviewed and supplemental data added as needed to create the Tier IIIA dataset.

These include the following:

- Depth interval
- Preparation for analysis (e.g., digestion method)
- Analytical method
- Geology and parent soil material

- Sample type (e.g., grab, composite, incremental soil composite)
- Particle size (e.g., <2 mm, <150 μm)

Of these, only the depth interval and particle size are exclusionary criteria established in the DQOs. At this point, the seven samples collected from depths greater than 6 in. were removed from the dataset because the number was deemed insufficient to justify relaxing the depth interval considered. All samples in this dataset met the particle size criterion. This group of samples and results are referred to as the Tier IIIA dataset, which was then reviewed to evaluate suitability as a single dataset. Potential influence of geology and soil parent material are important factors to assess if specific data are representative of background conditions in the upland soil study area. Although these factors were not used to screen in or out samples and results in the Tier IIIA dataset, it may be necessary to consider these factors as part of a refinement of the background dataset as part of the site characterization that will be included in the RI report. These factors are discussed further in Section 2.3.7.1 of this memorandum.

2.3.6.1 Assessing Methods of Sample Preparation and Analysis

The methods of sample preparation and analysis were researched for each of the remaining studies, and generally fit into four categories: total metals, partial digestion (also known as total-recoverable), loss on ignition (LOI) plus digestion (Wells 2015), and mercury. These distinctions are meaningful because each has the potential to extract a different portion of the sample depending on particle size and the mineral phases in the soil (Fishman and Friedman 1989; Ames and Prych 1995; USEPA 1996; Smith et al. 2009). These sample preparation groupings are shown in Table 3 for the Tier IIIA studies along with the number of results in each category. Locations for all metal and metalloid results are shown by study in Figures 4a through 4t.

The total metals category includes methods that aim to measure the entire concentration of an element in a sample, which includes biologically available metals as well as the full mineral content of the soil (i.e., mineral grains). These methods include INAA, which was used for many of the NURE-HSSR soil and sediment samples,[15] and "total digestion", which was also used for NURE-HSSR samples and the USGS studies Smith (2006), USGS (2008b), and Smith et al. (2013). The total digestion methods use strong acids such as hydrofluoric and perchloric acids to achieve a high percent recovery for an element (95 percent; Ames and Prych 1995).

The partial digestion category includes methods designed to liberate "most material bound by surficial coatings on soil particles but removes less than 95 percent of the metals from the mineral matrix" (Ames and Prych 1995; Smith et al. 2009). This includes EPA Method 3050 (USEPA 1996). Although partial digestion methods also use strong acids, they may not achieve the high recoveries seen with total digestion methods. Wells (2015) is unique in that the volatile portion of the sample was measured by LOI before the sample was digested by microwave

[15] Elements by INAA included only aluminum, iron, manganese, sodium, and vanadium.

assisted nitric acid digestion. By oxidizing the sample before digestion, the dissolution properties of the samples are modified.

Additional review of sample preparation methods suggests that some samples underwent additional treatment before dissolution. This includes the reanalysis of archived NURE samples in Church et al. (2008; Study "CHURC08A"). Further examination of how samples were prepared for the NURE-HSSR program shows samples prepared for chemical analysis at Savannah River Laboratory were not only sieved to -100 mesh (<150 μm) but were also ground to -500 mesh in a ball mill (Grimes 1984; Figure 3.12). Whether the reanalyzed samples were from an unground archived split or a finer -500 mesh split is unknown. The latter finer sample would facilitate sample dissolution because of the increased surface area of all portions of the sample (matrix and mineral content).

Metal and metalloid concentrations are shown in boxplots in Attachment B. Results were grouped into the sample preparation categories: INAA, total digestion, LOI+digestion, and partial digestion. Incidentally, the total digestion methods are used on almost all samples with particle size <150 μm;[16] while the partial digestion methods were a mixture of samples with particle sizes <2 mm and <150 μm. There are variations in concentrations between methods and size fraction (see Attachment B for statistical analyses); thus, the results were segregated by total metals, partial digestion, and mercury. LOI+digestion results were excluded because they are not comparable to the other studies considered. The results retained for the Tier IIIB dataset include samples analyzed by INAA, AAS, ICP-AES, and ICP-mass spectrometry (MS), which are considered equivalent methods.

2.3.6.2 Assessing Sample Type

The Tier IIIA dataset has three general sample types: grab (i.e., independent, discrete), composite, and incremental composite samples (ICS). Grab samples by definition represent a point location. Composite samples in the Tier IIIA dataset generally represent a composite of five or more samples collected from areas of varying size. In contrast, the ICS method (ITRC 2012) used for the 2014 Upland Soil Study (TAI 2015b, Study "Teck_2014_UplandSoil") consisted of 30 subsamples per decision unit, which were approximately 25 acres in size. The screened dataset at this stage includes 15 grab samples from three studies, 23 areas sampled by ICS for the 2014 Upland Soil Study, and over 3,200 composite sample locations (Table 4). Each of the sample types represents background concentrations on a different spatial scale, but in combination characterize concentrations throughout the study area.

[16] All but six of the samples for total digestion represent the <150 μm size fraction.

2.3.6.3 Assessing Particle Size

The Tier IIIA dataset includes samples sieved to <2 mm and <150 μm which are most representative for ecological and human health exposures, respectively. There was no need for further exclusions based on particle size.

The 2014 Upland Soil Study measured metals and metalloids for samples from both size fractions (<2 mm and <149 μm), many from the same location (Table 4). To avoid over-weighting these locations, the <2 mm samples were retained in the Tier IIIB dataset and used for derivation of BTVs (i.e., <149 μm results from 2014 Upland Soil Study are not used in this assessment).

2.3.7 Geospatial Consistency of the Tier IIIB Dataset

Geospatial sample characteristics merged with the measured metal and metalloid concentrations provide the starting dataset for evaluations to determine consistent groups of samples (i.e., populations) for characterizing BTVs for each element. The original objective of statistical comparisons based on geospatial classifications was to identify groups of samples that represent significantly different conditions that would justify separate risk evaluations for sub-areas of the Site. The Tier IIIB dataset consists of samples from two particle sizes, multiple sample types, and various preparation and analysis methods, in addition to other differences in sampling between studies. The screened background data were evaluated for differences between assessment variables as stated in the DQOs (TAI 2018b) as follows:

- Maps of metal concentrations with geospatial classifications to visually assess variability across the region.
- Analysis of variance (ANOVA) based on metal concentrations to determine significant differences between geospatial classifications.

2.3.7.1 Spatial Variability

Maps showing sample concentrations[17] of each metal and metalloid (Figures 5a through 5t) demonstrate the spatial variability in concentrations across the study area. This variability is likely the result of several confounding factors that makes the interpretation of metals concentrations in surface soils in the areas surrounding the UCR challenging. The overemphasis of a single factor (e.g., particulate deposition from smelter emissions) to the occurrence of metals in a specific part of the UCR Site may lead to an inaccurate assessment of background conditions that are relevant to the upland soil dataset.

Geologic formations enriched in lead and zinc, in mineable concentrations, are present in the UCR area, and are often associated with calcareous materials, such as limestone and dolomite.

[17] This subset of metals is provided for consistency with the earlier maps demonstrating sampling locations.

The occurrence of formations enriched in lead and zinc is reported in Lovering (1976), not as uniform occurrences in country rock, but in mineralized zones where the emplacement of lead has occurred regionally. These formations are prevalent in the Northport and Metaline mining districts, located in Stevens County and Pend Oreille County, respectively, and are found throughout the northeastern portion of WRIA 61 and extending north into Canada. This area is part of the principal lead deposits in the continental United States and along with southeastern British Columbia, Canada, and northern Idaho comprise "one of the great lead-zinc provinces of the world" (Lovering 1976; Weissenborn et al. 1970, p. 3). Furthermore, Mills (1977) identified 98 mines and prospects in Stevens County, mostly within carbonate rocks associated with the Kootenay Arc that extends from southern British Columbia into northeastern Washington, indicating widespread occurrences of bedrock assemblages in the UCR area. An example of this is the Metaline Limestone of Middle Cambrian age, which is the host for all stratiform lead and zinc in in Stevens County (Mills 1977). These lead-zinc deposits transition in eastern Stevens County and into Pend Oreille County, to occurrences that are associated with more meta-granitic deposits (Jenkins 1924).

Quaternary surface deposits in the UCR have likely been partially derived from weathered bedrock formations and transported by glacial and hydraulic events and are therefore widely distributed across the UCR Site and likely influence local natural background concentrations. Therefore, soil parent material and underlying bedrock are significant factors influencing the natural background level of trace metals in the UCR area, specifically in Stevens County, where high concentrations of lead, zinc, and other associated metals have been historically observed in this area (see Figure 6). Consideration of these factors is beyond the scope of this memorandum, however, consideration of geologic and geochemical factors may be warranted as part of a future refinement of the background assessment and for use in the RI. Additional evaluation of soil compositions may be presented in the RI report if necessary to support a refinement of the background assessment.

Consideration of bedrock geology as an explanatory variable for elevated soil metals concentrations in a specific area is consistent with the approach used by Ecology (2019), where elevated chromium concentrations in WRIA 60 are attributed to the presence of chromium-bearing ultramafic mineralization within tributaries of this WRIA. In this case, chromium results from WRIA 60 were not eliminated. Instead, the authors state that "caution is advised for chromium background range applications, as the maximum value in particular may be best reserved to WRIA 60 only" (Ecology 2019, p. 49).

2.3.7.2 Analysis of Variance

Formal statistical comparisons of differences among assessment variables (sample preparation and analysis methods, sample type, particle size, WRIA, land use, and geology) using ANOVA were confounded by the multiple aspects that differ between studies. Attributing differences to one of the assessment variables is misguided and segregating by study does not provide the desired geographic coverage of the study area (see Attachment B for ANOVA by sample preparation and analysis method). Table 4 indicates the number of sampling locations by

particle size, sample type, and WRIA. This dataset includes samples from 20 land use types, 43 geology classifications, and 62 soil map units. The imbalanced distribution of samples between categories, along with other differences between studies, confounds interpretation of ANOVA results, therefore no formal statistical comparisons were evaluated.

2.3.7.3 Upgradient Features

As stated in the DQOs, distance to various upgradient features was added to the dataset to help in the assessment of impacts from upgradient runoff. For the Tier IIIB dataset, none of the sample locations are in the flow path of a mine or mill, or landfill as described in Section 2.3.5. Only four locations are downgradient from railways (one almost 3 km away), while over 360 locations are downgradient from roads (most over 100 m away). However, the setback of 50 m for these is likely sufficient to avoid contamination without over screening samples for the assessment. As such, these features are unlikely to affect downgradient samples retained for the final natural background dataset.

2.3.8 The Tier IIIC Dataset

In their May 29, 2020 comments, EPA required additional partial digestion sample results be removed from the Tier IIIB dataset; no further refinements were required for the total digestion and mercury results. The exclusions are based on multivariate analyses conducted by EPA that used partial digestion sample results for selected metals and metalloids[18] (see Tables 3 and 4 regarding samples from Church et al. 2008[19]; Ecology 1994, 2013b; USEPA 2002c; TAI 2015b[20], Wells 2015). EPA's analyses also included air deposition area (ADA) sample results, from the 2014 Upland Soil study, located within the 1931 SO_2 plume area as determined by EPA (USEPA 2020c, Attachment 1). By applying this screening step, additional samples beyond the 1931 SO_2 plume area were removed, which included all partial digestion results for samples located in WRIA 61 plus two samples from other WRIAs.[21]

2.4 Background Threshold Values

BTVs were calculated as one-sided 95 percent upper confidence limit on the 95th percentiles, or 95/95 upper tolerance limits (UTLs), of the Tier IIIC dataset using ProUCL 5.1 (USEPA 2015a,b), as specified in the DQOs (TAI 2018b). Quantile-Quantile (QQ) plots of measured or

[18] Metals and metalloids included were aluminum, arsenic, beryllium, cadmium, chromium, copper, iron, lead, manganese, nickel, and zinc.

[19] EPA's analyses also include Sample DSOR460S1, which was excluded from Tables 3 and 4 because of its proximity to the Midnite Mine (i.e., total number of samples EPA used from Church et al. [2008] was 44).

[20] Particle size less than 2 mm (i.e., 23 samples outside the 1931 SO_2 plume area).

[21] For WRIA 61, this includes 17 samples from the 2014 Upland Soil Study ("Teck_2014_UplandSoil" samples; TAI 2015b) and 8 samples from the Van Stone Mine remedial investigation ("HARTC13C" samples; Ecology 2013b). The additional samples are Sample RZAH028S1 located in WRIA 54 (Church et al. 2008) and Sample MJ0FL1 located in WRIA 62 (USEPA 2002c).

log-transformed metal concentrations, depending on distributional assessment, were used to identify anomalous high concentrations that would overly influence the BTV in conjunction with formal outlier tests (i.e., Dixon or Rosner tests). Input data, output from ProUCL, and QQ-plots are provided in Attachment C: Attachment C-1 provides these materials based on the total metals results, Attachment C-2 based on the partial digestion results, and Attachment C-3 based on the mercury results. Each attachment includes summary statistics, goodness-of-fit distributional assessments, results of the outlier assessments, and the BTV with the calculation method for each metal and metalloid.

Table 5 summarizes the BTVs derived for each metal and metalloid for the total metals, partial digestion, and mercury results. BTVs with and without identified outliers are included in the table. An additional BTV for arsenic is included that reflects exclusion of five samples identified by EPA based on their multivariate analyses (USEPA 2020c, Attachment 1). As discussed in Section 2.3.7.1, the background dataset is complex. Therefore, the initial assessment of the contribution of natural background will be assessed using the BTVs presented in Table 5 that were derived from the Tier IIIC dataset. Recognizing the uncertainty in these BTV estimates, a refinement that takes into consideration the numerous physical, chemical, and geological factors present in the UCR area will be completed, if necessary, during preparation of the site characterization and RI reports. Confounding factors such as contributions from soil material that is naturally enriched with metals, spatial variability of aerial deposition (due to meteorological conditions, barriers to dispersal such as topography, slope orientation, and distance from area and point sources) may be used to identify data with attributes that indicate they are appropriate for the determination of refined background values and should be incorporated into the background dataset.

3 Exploratory Area Background Evaluation

The previous sections describe the analysis conducted to establish natural soil background concentrations for use in the RI/FS and risk assessments. As defined above and under MTCA (WAC 173-340-200), “natural background means the concentrations of hazardous substances consistently present in the environment that have not been influenced by localized human activities.” However, in addition to natural background, the RI and the BERA require an evaluation of non-site related anthropogenic influences on soil chemistry, i.e., area background. Under MTCA, “Area background means the concentrations of hazardous substances that are consistently present in the environment in the vicinity of a site, which are the result of human activities unrelated to releases from that site.” Evidence for area background is a correlation between non-site-related anthropogenic sources of metals and metalloids and local or regional background concentrations. If a correlation exists, the magnitude and spatial distribution of area background can be determined.

The first step in the exploratory area background evaluation was to develop a preliminary understanding of the potential for anthropogenic features and/or land use to influence area background soil metals concentrations. Figure 7 includes a map showing the 1931 SO_2 plume

area that established the boundary of the 2014 Upland Soil Study (TAI 2015b). This figure also shows the distribution of land use classifications (e.g., residential, manufacturing, mining, agriculture, etc.) and presence of anthropogenic features (e.g., active and inactive mines, mills, and smelters; roads; and railways) within and in the immediate vicinity of the 1931 SO_2 plume area. Based on Figure 7, the following observations were made:

- Land Use Classification
  - Land use inside and outside of the 1931 SO_2 plume area is primarily classified as undeveloped or public/private forest.
  - Residential and agricultural land uses are also represented.
  - Manufacturing and retail land uses are represented less frequently than residential or agricultural lands and are located primarily within or adjacent to the nearby towns of Colville and Kettle Falls.
  - The mining land use is represented in one location in the northeast corner of Figure 7 that appears to be associated with the inactive Anderson Calhoun Mine/Mill.
- Anthropogenic Features
  - Despite the infrequent occurrence of the mining land-use classification, there are a number of active and inactive mines, mills, and smelters inside and outside of the 1931 SO_2 plume area (e.g., Last Chance Mine & Mill, Young America Mine & Mill, etc.).
  - There are several secondary roads inside and outside the 1931 SO_2 plume area, including Highway 25, which runs parallel to the UCR directly down the middle of the 1931 SO_2 plume area. Highways 20 and 395 are also present within the immediate vicinity of the 1931 SO_2 plume area.
  - There are pervasive local paved and unpaved roads inside and outside the 1931 SO_2 plume area.
  - There is a railway that runs parallel to the UCR and Highway 25 directly down the middle of the 1931 SO_2 plume area, and another railway that runs parallel to Highway 395 to the west of the 1931 SO_2 plume area.

The presence of anthropogenic land uses (e.g., residential, agricultural) coupled with the numerous active and inactive anthropogenic features within and immediately adjacent to the 1931 SO_2 plume area strongly suggest that current and/or historical anthropogenic activities may have influenced area background soil metals and metalloids concentrations. An exploratory evaluation of the factors that may influence area background is summarized below.

3.1 Area Background Dataset

The Tier I dataset plus added location-based information described in Section 2.3.4 was used to derive the exploratory area background dataset. Many of the Tier II exclusion criteria that were applied to the natural background dataset were designed to eliminate samples associated with anthropogenic activities and features. As the goal of the area background evaluation is to characterize the effects of anthropogenic activities and features, most of the Tier II exclusions were not applied to the exploratory area background dataset.

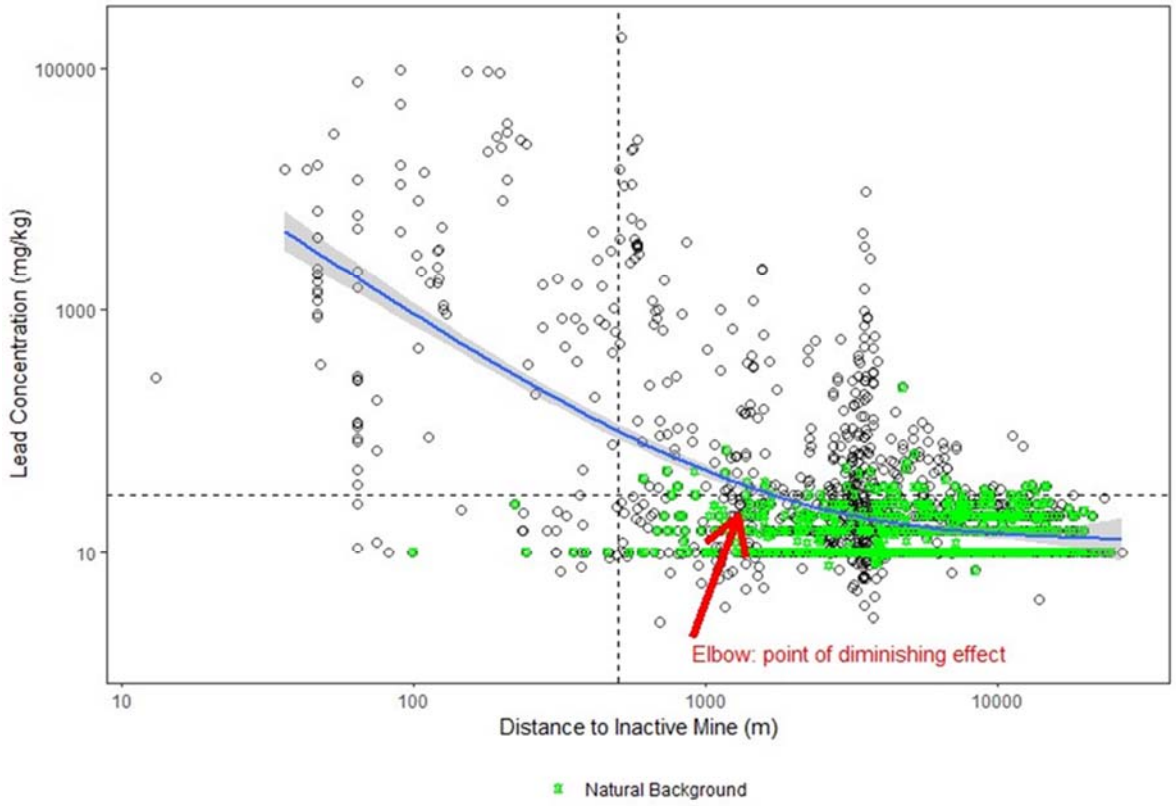
Although the analytical and digestion methods (i.e., samples prepared using total digestion versus partial digestion methods) may bias the results, due to the large number of samples, spatial coverage, and consistent sample preparation and analytical methods within the NURE-HSSR dataset, it is useful for examining spatial correlation between metals and metalloids concentrations and potential anthropogenic sources. Additionally, the NURE-HSSR samples were collected between 1977 and 1979, which may be before more recent and current anthropogenic sources were present, and this will be considered when interpreting the NURE-HSSR results relative to specific anthropogenic features.

3.2 Example of Anthropogenic Influences on Soil Metals and Metalloids Concentrations

The exploratory area background evaluation included an assessment of the relationship between soil metals and metalloids concentrations and proximity to anthropogenic features. An example of this preliminary analysis focused on the proximity of inactive mines related to soil metals and metalloids concentrations. It was assumed that if inactive mines contribute to elevated soil metals and metalloids concentrations, then concentrations would be highest close to inactive mines, concentrations would decrease with increased distance from the inactive mines, and concentrations would eventually level off at distances beyond the mine zone of influence. Plots of concentrations as a function of distance from inactive mines were used to assess this relationship. Figure 8 (inset on the following page) shows an example with lead concentrations plotted against distance from inactive mines in soil samples collected outside the 1931 SO_2 plume area. A generalized additive model (GAM[22]) was used to fit a flexibly shaped curve that shows the general trend in concentrations across distance from the inactive mines (blue line in Figure 8).

As shown on Figure 8, the expected distribution of concentrations with distance from inactive mines was observed for lead. This suggests that inactive mines do, indeed, have an effect on soil metals and metalloids concentrations. Similar results were observed for lead, zinc, and copper

[22] A GAM uses splines to fit flexibly shaped curves that are particularly useful in initial data analysis and exploratory analyses. They are well suited to reveal potentially curvilinear relationships that are not restricted to the shapes imposed by typical straight line or polynomial regression models.



with distance from active and inactive mines and mills for soil outside the 1931 SO_2 plume area, and when the entire soil dataset was evaluated.

The distance at which concentrations stabilize is expected to be the point at which samples are beyond the mine zone of influence (as indicated by the point of diminishing effect illustrated by the GAM curve; see the arrow in Figure 8). This example suggests that the mine zone of influence may extend beyond the 500-m buffer zone used for the Tier II exclusions.

This exploratory evaluation included data from multiple observational studies that were performed for different purposes over many years, and the data did not fall neatly into categories that could be carefully controlled. Therefore, there is a potential for confounding factors that may influence conclusions. These potential confounding factors that may influence area background will be further evaluated as necessary in the site characterization summary and integrated into the RI report, which TAI will prepare in the future as required by Section V, Paragraph 13.c of the Settlement Agreement, Task 3 – Site Characterization (USEPA 2006a).

3.3 Summary of Exploratory Area Background Evaluation

This example suggests that some anthropogenic features within and immediately adjacent to the 1931 SO_2 plume area may have influenced area background soil metals and metalloids concentrations. However, further analysis is warranted to ensure multiple anthropogenic effects are not confounded in such a way as to mask or exaggerate the effects of the individual features. Area background will be comprehensively evaluated and discussed in the site characterization summary and RI report using techniques such as principle component analysis.

Notes: The vertical dashed line represents the 500-meter mine buffer, and the horizontal dashed line represents the natural background UTL for lead. Samples included in the natural background dataset are shown in green. The red arrow indicates the inflection point of the GAM curve that represents the point at which concentrations stabilize outside the mine zone of influence. The grey shading indicates the 95% confidence interval of the GAM fit.

GAM - generalized additive model
UTL - upper tolerance limit

Figure 7. Land use and mining within the 1931 SO_2 plume area

Figure 8. Lead concentrations as a function of distance from inactive mines (inset at the end of the main text)

Apply Tier I Screening
- Matrix: All soil and NURE-HSSR sediment samples collected ≤24 in. depth
- Within WRIAs 49, 51, 52, 53, 54, 55, 58, 59, 60, 61, and 62
- Aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, thallium, vanadium, and zinc

→ **Tier I Dataset**

Apply Location-Based Screening Criteria
- Outside 1931 SO_2 plume area
- Distance to nearest road ≥50 m away
- Distance to nearest railway ≥50 m away
- Distance to nearest landfill ≥500 m
- Distance to nearest mine or mill as defined by latitude and longitude location (i.e., a point) in the Mineral Resources Data System (MRDS) ≥500 m as follows:
  - Producers
  - Past producers
  - Plants
  - Locations designated as "unknown" development status
- Distance to nearest landslide—Outside footprint
- Outside 100-year floodplain

→ **Tier IIA Dataset**

Apply Supplemental Tier II Screening
- Replicate samples averaged
- Retain NURE-HSSR samples that were reanalyzed over the original results from the 1970s with the exception of silver for which the older analysis had lower detection limits.
- Remove replicate results for arsenic by two methods for Study ID geochem-fU53 (AA retained over ICP because AA had lower detection limits)
- Additional review of samples near Van Stone, Sierra Zinc, Pend Oreille, Yellowhead, and Midnite Mines for ≥500 m setback

→ **Tier IIB Dataset**

Supplemental Tier III Screening
Add (if needed) sample and analysis Information
- Screen for 0–6 in depth interval (lower depth ≤6 in)
- Review and screen for particle size (no exclusions)
- Review and categorize sample preparation and analysis methods

→ **Tier IIIA Dataset**

Data Review and Statistical Assessment
- Boxplots by analysis category, by metal
- Analysis of variance for significant differences, by metal

→ Total Metals Methods
→ Partial Digestion Methods (EPA 3050 or Equivalent)
→ Mercury
→ **Tier IIIB Dataset**

Comparability Assessment
- Review underlying geology and soil parent material
- Review sample type
  - 25 acre 30-point composite (TAI 2014)
  - 5-point composite
  - Single grab
- Review material analyzed (<2 mm and <150 µm)

Removal of Partial Digestion Results Identified by EPA
- All results for samples in WRIA 61 prepared by partial digestion (25 samples from TAI [2015b] and Ecology [2013b])
- Results for Sample RZAH028S1 from Church et al. (2008)
- Results for Sample MJ0FL1 from USEPA (2002c)

→ **Tier IIIC Dataset**

Background Assessment by Comparable Sample Group
- All Total Metals samples
- All Partial Digestion samples
- Mercury

ProUCL background assessment for 95/95 upper tolerance limit (95% upper confidence limit on 95th percentile)

General land use codes used in Figure 7

General Land Use Category	Code	Description
Residential	11	Household, single family units
	12	Household, 2-4 units
	13	Household, multiunits (5 or more)
	14	Residential condominiums
	15	Mobile home parks or courts
	16	Hotels/motels
	17	Institutional lodging
	18	All other residential not elsewhere coded
	19	Vacation and cabin
Manufacturing	21	Food and kindred products
	22	Textile mill products
	23	Apparel and other finished products made from fabrics, leather, and similar materials
	24	Lumber and wood products (except furniture)
	25	Furniture and fixtures
	26	Paper and allied products
	27	Printing and publishing
	28	Chemicals
	29	Petroleum refining and related industries
	30	Rubber and miscellaneous plastic products
	31	Leather and leather products
	32	Stone, clay and glass products
	33	Primary metal industries
	34	Fabricated metal products
	35	Professional scientific, and controlling instruments; photographic and optical goods; watches and clocks-manufacturing
	36	Not presently assigned
	37	Not presently assigned
	38	Not presently assigned
	39	Miscellaneous manufacturing
Transportation; Utilities	41	Railroad/transit transportation
	42	Motor vehicle transportation
	43	Aircraft transportation
	44	Marine craft transportation
	45	Highway and street right of way
	46	Automobile parking
	47	Communication
	48	Utilities
	49	Other transportation, communication, and utilities not classified elsewhere
Retail; Services	50	Condominiums - other than residential condominiums
	51	Wholesale trade
	52	Retail trade - building materials, hardware, and farm equipment
	53	Retail trade - general merchandise
	54	Retail trade - food
	55	Retail trade - automotive, marine craft, aircraft, and accessories
	56	Retail trade - apparel and accessories
	57	Retail trade - furniture, home furnishings and equipment
	58	Retail trade - eating and drinking
	59	Other retail trade
	61	Finance, insurance, and real estate services
	62	Personal services
	63	Business services
	64	Repair services
	65	Professional services

General land use codes used in Figure 7 (Continued)

General Land Use Category	Code	Description
Retail; Services (*Cont.*)	66	Contract construction services
	67	Governmental services
	68	Educational services
	69	Miscellaneous services
Culture; Recreation	71	Cultural activities and nature exhibitions
	72	Public assembly
	73	Amusements
	74	Recreational activities
	75	Resorts and group camps
	77	Not presently assigned
	78	Not presently assigned
	79	Other cultural, entertainment, and recreational
	84	Fishing activities and related services
Agriculture	81	Agriculture (not classified under current use law)
	82	Agriculture related activities
	83	Agriculture classified under current use chapter 84.34 RCW
Mining	85	Mining activities and related services
Parks; Undeveloped	76	Parks
	94	Open space land classified under chapter 84.34 RCW, also public owned land; wildlife refuges, DNR range land, other open space
	91	Undeveloped land
	99	Other undeveloped land
Public Forest	87	Public forest land
Private Forest	88	Designated forest land under chapter 84.33 RCW
	92	Noncommercial forest
	95	Timberland classified under chapter 84.34 RCW

Notes: Land use codes from Ecology (1994)

Final Data Quality Objectives for Determination of Background Metal and Metalloid Concentrations in Upland Soil (TAI 2018b)

Final Data Quality Objectives for Determination of Background Metal and Metalloid Concentrations in Upland Soil

Introduction

The upland soil background assessment will provide information on the range of soil concentrations for metals and metalloids[1] that are representative of natural background in and around the Upper Columbia River (UCR) Site (hereafter the Site[2]). This assessment is one of numerous tasks to be completed as part of the UCR remedial investigation and feasibility study (RI/FS) and baseline ecological risk assessment being conducted by Teck American Incorporated (TAI). This assessment will also inform the human health risk assessment that is being conducted by the U.S. Environmental Protection Agency (EPA) (USEPA 2006a, 2016). The purpose of this document is to summarize the data quality objectives (DQOs) identified for the upland soil background assessment. The primary objective for this assessment is to ascertain the natural background soil concentrations as defined by Washington State (WAC 173-340-200[3])

---

[1] The metals and metalloids assessed will include those listed in the Upper Columbia River Soil Study (TAI 2015) Table 2-1, which are aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, mercury, nickel, potassium, selenium, silver, sodium, thallium, vanadium, and zinc. Thus, in this document "metals and metalloids" refers only to this list of elements. These metals and metalloids were identified as chemicals of interest for the referenced soil study and therefore all of these elements will be included in the assessment of natural background soil concentrations to provide the appropriate context for interpretation of the soil analytical results. Additionally, cation exchange capacity (CEC) is calculated from potassium, magnesium, calcium, sodium, and hydrogen (pH) concentrations in soils, and can be used (along with pH) to understand the natural bioavailability of metals in soils in the study area.

[2] The UCR Site as defined within the June 2, 2006 Settlement Agreement (USEPA 2006a) is the areal extent of hazardous substances contamination within the United States in or adjacent to the Upper Columbia River, including the Franklin D. Roosevelt Lake, from the U.S.-Canada border to the Grand Coulee Dam, and those areas in proximity to the contamination that are suitable and necessary for implementation of response actions.

[3] WAC 173-340-200:

"Natural background" means the concentration of hazardous substance consistently present in the environment that has not been influenced by localized human activities. For example, several metals and radionuclides naturally occur in the bedrock, sediments, and soils of Washington state due solely to the geologic processes that formed these materials and the concentration of these hazardous substances would be considered natural background. Also, low concentrations of some particularly persistent organic compounds such as polychlorinated biphenyls (PCBs) can be found in surficial soils and sediment throughout much of the state due to global distribution of these hazardous substances. These low concentrations would be considered natural background. Similarly, concentrations of various radionuclides that are present at low concentrations throughout the state due to global distribution of fallout from bomb testing and nuclear accidents would be considered natural background.

"Area background" means the concentrations of hazardous substances that are consistently present in the environment in the vicinity of a site which are the result of human activities unrelated to releases from that site.

and the EPA (USEPA 2002[4]). Soil conditions, including concentrations of metals, minerals, and nutrients, are major determinants of plant communities. (Other determinants include, but are not limited to, soil moisture, soil texture, temperature, and sunlight.) Therefore, it is not possible to conclude "risk" to plant communities if metals, minerals, and nutrients are at natural background levels, even if these concentrations are higher than those determined through laboratory toxicity tests to result in phytotoxicity in test species. Species that are sensitive to certain metals, minerals, or nutrients simply will not be present in areas that have naturally high concentrations of these substances. Plant communities, in turn, are determinants of animal (invertebrate and vertebrate) communities, which also should not be considered at risk when metal concentrations in soil are at naturally occurring levels. Knowledge of natural background concentrations for UCR soils can be applied during the RI/FS process by removing from further consideration those areas where measured soil concentrations of the contaminants of potential concern are no higher than natural background. Areas where concentrations are higher than natural background would be further evaluated to determine which species/communities are likely to be at risk from the elevated concentrations of metals or minerals in soils.

In 2016, EPA prepared and provided TAI with a "level of effort" (LOE) memorandum that outlined an approach to compiling a background dataset from preexisting data sources along with DQO Steps 1to 3 for that process (USEPA 2016). In the memorandum, EPA evaluated 13 studies that may be usable in compiling a background dataset for the Site. EPA's primary criteria were that all samples should have a known location (i.e., known spatial coordinates and depth) that is near the UCR, but is outside the pre-dam 100-year floodplain, the historical sulfur dioxide (SO_2) smelter injury footprint described by Scheffer and Hedgcock (1955), areas disturbed by human activity, and possibly natural forces such as landslides. Data that met these initial screening criteria were evaluated further with respect to sample collection method, chemical analysis methods, and detection limits. This document expands upon EPA's LOE memorandum (USEPA 2016). As stated above, the results of the background assessment will inform future tasks and analyses related to assessing ecological and human health risks.

Data Quality Objectives

Step 1—State the Problem

The determination of natural background concentrations of metals and metalloids in upland soils is needed for use in the RI/FS as stated above. The analysis will determine natural background concentrations of metals and metalloids in soil consistent with the definition of *natural background* contained in the Washington State Model Toxics Control Act (MTCA).[1] This

[4] USEPA (2002) defines background as "constituents or locations that are not influenced by the releases from a site, and is usually described as naturally occurring or anthropogenic (EPA, 1989; EPA, 1995a):

1) *Anthropogenic* – natural and human-made substances present in the environment as a result of human activities (not specifically related to the CERCLA release in question); and,

2) *Naturally occurring* – substances present in the environment in forms that have not been influenced by human activity."

includes anthropogenic influences from large-scale diffuse sources (e.g., mercury, PCBs, dioxin), but eliminates local or point source anthropogenic input. The area for the UCR background assessment is a large, heterogeneous area, which makes it difficult to account generally for local anthropogenic inputs. These include point sources such as aerial transport and deposition from smelter stack emissions from the Teck operations at Trail, BC, and those of the LeRoi/Northport smelter in Northport, WA. Therefore, as detailed in this DQO, soil data from areas in or near roads, railroads, mines, mills, or comparable sites will not be used. Similar to the approach presented by EPA in the LOE memorandum (USEPA 2016), soil data within the area delineated as injured by sulfur dioxide (SO_2) emissions from the 1920s into the1930s will be avoided to remove the potential for including samples that might be affected by aerial deposition from smelter stack emissions in the past. The remaining areas from which soil measurements will be used for background determination are remote from human influence and can be considered representative of natural background. Natural mineralization in the area that contain enrichment of some of the metals and metalloids of interest and related to geogenic processes will be clarified as part of the process of defining natural background concentrations. Further analysis of metal and metalloid concentrations in UCR soils is needed to identify those areas where measured soil metal and metalloid concentrations are at or below natural background and areas where concentrations are higher than natural background, and to inform the UCR remedial investigation and the ecological and human health risk assessments.

Step 2—Identify the Goals of the Study

The study goal is to compile a dataset of soil metal and metalloid concentrations from northeast Washington State that are of sufficient data quality to calculate summary statistics needed for assessing the nature and extent of soil concentrations above natural background levels and for assessing ecological and human health risks in these areas.

Step 3—Identify Information Inputs

The data sources to be considered include the following:

- Data from studies identified in EPA's LOE memorandum
- Studies referenced in other TAI UCR reports, as well as studies prepared for Teck Metals' Trail operations
- UCR-RI/FS database
- Washington State Department of Ecology (Ecology) Environmental Information Management System (EIM) data from northeastern Washington (Ecology 2018)

- National Uranium Resource Evaluation (NURE)–Hydrogeochemical and Stream Sediment Reconnaissance (HSSR) dataset (Smith 2006)[5]
- U.S. Geological Survey (USGS) databases and datasets including the National Geochemical Database (USGS 2016), the National Geochemical Survey (USGS 2008), and the North American Soil Geochemical Landscapes Project (Smith et al. 2013). These include the NURE reanalysis data for Washington State (NURE 2000 dataset[6]), cooperative efforts by the USGS and the Washington State Department of Natural Resources (DNR) encompasses the States 2004, 2005, 2006a datasets, data from the PLUTO database,[7] and low density geochemical and mineralogical soil survey data.
- Canadian datasets available online
  - British Columbia Soil Information System (BCSIS; Province of British Columbia 2014)
  - British Columbia Ministry of Environment (BCME 2016)

See Attachment A for the specific data sources under consideration.

Step 4—Define the Boundaries of the Study

Surface soil samples from a broad area in northeastern Washington on either side (east and west) of the Columbia River will be considered in terms of their data quality and relevance. Data from studies conducted near the Columbia River will be given preference, but soil samples from farther away may be needed to verify that the closer-in data represent natural background and have not been influenced by the Trail or LeRoi/Northport smelters. The surficial soil layer is of greatest relevance to the ecological and human health risk assessments. As such, concentration data for surface soils are preferred; samples collected deeper than 6 in. will be critically reviewed and included in the dataset for the background assessment only if they are needed to fill data gaps.

Step 5—Define the Analytic Approach

This study has three steps:

- Compile the dataset.

---

[5] Based on recommendations from EPA made at the October 2, 2017 meeting, data from the hydrogeochemical and stream sediment reconnaissance (HSSR) phase of the NURE program will be considered.

[6] USGS (2008), "A suite of samples from across the entire US, pulled from the NURE archive and analyzed in 2000. Four week-long forays to the warehouse by 5-10 person teams were required to identify and package the samples. In doing these analyses, the NGS [National Geochemical Survey] extended work done at a regional scale in the southeastern US to a national scale effort. Most were analyzed by the ICP40, As, Se, and Hg methods. ~10% were also analyzed by INAA."

[7] USGS (2008), "The PLUTO database contains the results of analyses of geological material done by the Branch of Analytical Laboratories (and its successors and predecessors at the USGS) between the late 1960's and mid 1990's. PLUTO is one component of the National Geochemical Database at the USGS."

- Examine the data geospatially to verify that the samples are representative of natural background (i.e., they are not influenced by local anthropogenic sources) and determine whether combined they represent a homogenous population as a single set of data, or should be segregated into two or more distinct geographic areas based on the data attributes.
- Evaluate the data statistically to characterize background concentrations and identify a natural background threshold value for each of the metals/metalloids of interest.

Data Compilation

The dataset used to determine natural background soil concentrations will be evaluated using a tiered approach similar to that presented in EPA's LOE memorandum. The three tiers will include the following:

- Tier I—Samples should conform to the following:
  - Include geographic coordinates
  - Located in northeast Washington State
  - Be a soil matrix[8]
- Tier II—Add key supplemental data based on sample location to identify or avoid, if possible, geogenic and anthropogenic sources of the metals and metalloids of interest.
  - Pre-dam era 100-year floodplain, if available, or the 100-year floodplain will be used
  - Within or outside the historical SO_2 injury area (recording which "%Injury" zone; Scheffer and Hedgcock 1955)
  - For the NURE-HSSR samples, include the field judgement of possible contaminant sources or major activities near the sample site (CONTAMC field)
  - Distance to the nearest road
  - Distance to the nearest railway
  - Distance to the nearest mine
  - Distance to the nearest ore- or rock-processing mill
  - Distance to the nearest landfill
  - Geology
  - State of Washington Water Resources Inventory Area (WRIA) and Hydrologic Unit Code, plus the following physiographic features and built structures or features:
    - Distance to the nearest drainage feature within the same drainage

[8] For the NURE-HSSR dataset, the background dataset will not only consider soil, but also stream sediments.

        - Distance to the nearest mineralized area located upgradient in the same drainage
        - Distance to the nearest mill located upgradient in the same drainage
        - Distance to the nearest landfill located upgradient in the same drainage
        - Distance to the nearest road located upgradient in the same drainage
        - Distance to the nearest railway area or facility located upgradient in the same drainage
        - Distance to the nearest landslide upgradient in the same drainage
    - U.S. Department of Agriculture soil type
    - Land use
- Tier III—Add key sampling information to assess data compatibility and usability
    - Date of sample collection and sample depth
    - Sample type (e.g., grab/discrete or composite)
    - Size of particles analyzed (e.g., <2 mm, <149 μm)
    - Analytical suite (metals/metalloids only)
    - Digestion method
    - Analytical method

The supplemental data will be used to assess the influence of geogenic and anthropogenic sources as discussed above.

Geospatial Examination

Once all the data and their associated supplemental data have been tabulated and screened, soil concentrations will be used to determine background values for each metal and metalloid as follows. Maps will be generated to show concentrations overlaid with geospatial classifications, including drainage boundaries, geological classifications, and locations of anthropogenic alterations or disturbances. Analysis of variance[9] will be used to identify significant differences between the categories of each geospatial classification shown on the maps. Concentrations will be plotted to evaluate the distribution and analysis of variance used to identify significant differences between categories of each geospatial classification shown on the maps. Quantile-quantile (QQ) or cumulative distribution plots, with formal outlier tests (Dixon and Rosner,

[9] If the underlying assumptions of analysis of variance (ANOVA), specifically normality and homogeneity of variance, can be met using concentrations as measured or through a transformation (e.g., log) this will be preferred over using a non-parametric ANOVA such as Kruskal-Wallis. Comparison of results from both ANOVA methods can highlight overly influential samples or the impact of handling undetected analytical concentrations.

depending on the number of samples) if necessary, will be the basis to identify overly influential sample concentrations.

The geospatial analysis will determine if there are obvious differences between geographic regions (e.g., east versus west side of the Columbia River, specific drainages) or by underlying geology and evidence of anthropogenic alteration or disturbance. If no divisions are apparent, all of the data will be combined into a single dataset for the statistical analysis described below. However, if there is a technical basis to segregate the data, then the statistical analysis will be conducted separately on each group of data.

Background Threshold Values

Both the ecological and human health risk assessments include comparisons to background concentrations of metals and metalloids and rely on a background threshold value for screening. The ProUCL 5.1 (USEPA 2015) software is used by EPA regions, states, contractors, and stakeholders to summarize chemical concentrations in background soils and follows EPA guidance for developing background threshold values for use in risk assessments. A one-sided 95 percent upper confidence limit on the 95th percentile, or 95/95 upper tolerance limit (UTL), will be selected based on the distributional assessments and outlier evaluation from the multiple statistics provided in the ProUCL output. The report will include QQ or cumulative distribution plots along with a table of summary statistics, goodness-of-fit distributional assessments, and UTL concentrations for the entire dataset or geographically-limited subsets, depending upon the analysis described above, with and without identified outliers excluded. The complete output from ProUCL will be provided as an attachment to the report.

The complete steps of this analytical approach follow the approach described by EPA (2006b), for the entire dataset or more homogenous subsets that may be identified based upon the geospatial analysis.

Step 6—Specify the Performance Criteria

Geographical performance criteria in Tier II and III screening consists of the following, which are detailed in Table 1:

- Location undeveloped based on Ecology land use codes (see Table 1)
- Outside the SO_2 injury area
- WRIAs 49, 51, 52, 53, 54, 55, 58, 59, 60, 61, and 62
- Pre-dam era 100-year floodplain or 100-year floodplain—Outside
- Distance to the nearest road—At least 50 m away
- Distance to the nearest railway—At least 50 m away
- Distance to the nearest mine—At least 500 m away
- Distance to the nearest mill—At least 500 m away
- Distance to the nearest landfill—At least 500 m away

- Distance to the nearest landslide—Outside footprint

Sampling and chemical analytical methods described in Tier III will be assessed according to the following criteria:

- Analytical methods should be by inductively coupled plasma or atomic adsorption, and for selected NURE-HSSR results instrumental neutron activation analysis (INAA).
- Detection limits should be below screening values for human health and ecological risk assessments (see Table 2).
- Depth intervals of 0 to 1 in. and 0 to 3 in. are preferred, but sample depths up to 6 in. may be acceptable in areas where significant data gaps are identified.
- Other features (e.g., sample type, particle size, date of sample collection, digestion method) will be assessed for bias in concentrations using graphical and statistical summaries.

In the unlikely event that all data will be screened out by the above criteria, i.e., no acceptable samples are identified, TAI will revisit the criteria to determine which ones are the most restrictive. TAI will then refine the criteria to be less restrictive, recognizing that the resulting background values may be less robust and subject to greater uncertainty. TAI will discuss the refined criteria with EPA before rescreening the data.

Step 7—Develop a Plan for Obtaining the Data

Attachment A lists the studies under consideration for supplying data for the background assessment. Analytical results of the chemical concentrations for the metals and metalloids from these studies are already tabulated, but additional information may need to be added for some, such as sample collection or analytical methods, size of particles analyzed (sieve size), and depths. Some of the supplemental data listed in Tier II will be added following the initial geospatial analyses.

Supplemental data will be retrieved from sources such as:

- USGS (e.g., geology, mines, mills, prospects, watersheds, landfill, roads, railways)
- DNR (e.g., land use, landslides, inactive and abandoned mines) (Wolff et al. 2008)
- Ecology (e.g., water resource inventory areas, site investigations, removal actions)
- Federal Emergency Management Agency (e.g., floodplain maps)
- U.S. Department of Agriculture (e.g., soil surveys)
- Scheffer and Hedgcock (1955; SO_2 smelter injury footprint).

Attachment A

Information Under Consideration

Information Under Consideration

This attachment lists the documents and databases that will be considered for integration into the background soil dataset. The following general categories of studies are being reviewed:

- EPA's LOE memorandum (USEPA 2016)
- Studies referenced in other TAI reports prepared for the UCR remedial investigation and feasibility study, as well as studies prepared for Teck Metals' Trail operations that may inform the background assessment
- UCR-RIFS database
- EIM data from Northeastern Washington
- USGS Datasets
  - NURE- HSSR dataset
  - National Geochemical Database
  - National Geochemical Survey
  - North American Soil Geochemical Landscapes Project (Smith et al. 2013)
- Washington Division of Geology & Earth Resources.

Table 1. Exclusion and performance criteria details

Criteria	Type	Tier	Basis	Limits	Method/Resources
Location					
Geographic coordinates	Exclusion	I	Geographical coordinate information needed to identify proximity to potential contamination.	Present	Reported by individual studies and data repositories
Regional geographic location within northeastern Washington State	Exclusion	I	Bounds sample selection to the relevant area.	WRIAs 49, 51, 52, 53, 54, 55, 58, 59, 60, 61, and 62	Assign with ArcGIS—exclude outside of specified WRIAs (Ecology 2017)
Pre-dam era 100-year floodplain, if available or 100-year floodplain	Exclusion	II	Avoid areas that may include slag and effluent waste.	Floodplain perimeter	If the map can be located.
Historic SO_2 smelter injury zones	Exclusion	II	Avoid areas contaminated by historic smelter emissions.	Injury zone perimeter	Assign with ArcGIS—exclude inside of injury areas (Scheffer and Hedgcock 1955)
Land use	Exclusion	II	Avoid areas contaminated by residential, commercial, industrial, and natural resource extraction activities.	Land use codes 87, 88, 89, 91, 92, 93, 94, 95, 99[a]	Assign with ArcGIS—exclude outside of specified land use codes (Ecology 2010)
Soil type	Assessment	II	Soil type may affect sample composition.	None	Assign with ArcGIS (USDA 2016)
Geology	Assessment	II	Local geology may affect sample composition.	None	Assign with ArcGIS (USDA 2016)
NURE dataset contamination field	Exclusion	NA	Avoid areas contaminated by residential, commercial, industrial, and natural resource extraction activities.	Entry of “none” or “grazing”	Field from NURE-HSSR database—exclude entries beside “none” or “grazing” (USGS 2004)
Distance and gradient[b] to nearest					
Road	Exclusion	II	Avoid areas contaminated by historical use of leaded gasoline, imported roadbed materials, and fugitive dust from hauling loads without tarps or other containment.	50 m	Measure with ArcGIS—exclude within 50 m of road (USGS 2017)
Railway	Exclusion	II	Avoid areas contaminated by imported roadbed materials and fugitive dust from hauling loads without tarps or other containment.	50 m	Measure with ArcGIS—exclude within 50 m of railway (USGS 2017)
Landfill	Exclusion	II	Avoid areas contaminated by placement of waste materials on land surfaces.	500 m	Measure with ArcGIS—exclude within 500 m of landfill (USGS 2008)
Mine	Exclusion	II	Avoid areas contaminated by mining activities.	500 m	Measure with ArcGIS—exclude within 500 m of mine[c] (USGS 2005)
Mill	Exclusion	II	Avoid areas contaminated by milling activities.	500 m	Measure with ArcGIS—exclude within 500 m of mill[c] (USGS 2005)
Landslide	Exclusion	II	May have exposed materials not representative of surface or near-surface conditions.	Footprint perimeters	Measure with ArcGIS—exclude inside of landslide footprints (WADNR 2017)
Sample and analysis characteristics					
Matrix	Exclusion	I	Avoid mischaracterizing soil background by excluding non-soil matrices.	Soil[d]	Exclude non-soil matrices
Depth interval	Exclusion	III	The top 6 inches of soil is the active root zone, where plants take up nutrients (and contaminants) and where most soil microbes and invertebrates are found.	6 in	Exclude samples collected below 6 in
Sample type	Assessment	III	Sampling techniques may yield differential representativeness of the sample results (e.g., grab/discrete or composite).	None	Reported by individual studies and data repositories
Particle size	Exclusion	III	Particles larger than 2 mm are considered rock, not soil.	2 mm	Exclude sieve size >2 mm
	Assessment	III	Different particle sizes may result in different ranges for analytical results.	None	Reported by individual studies and data repositories

Table 1. Exclusion and performance criteria details

Criteria	Type	Tier	Basis	Limits	Method/Resources
Sample collection date	Assessment	III	Implications for analytical methods, detection limits, and potential nearby anthropogenic activities corresponding with the date.	None	Reported by individual studies and data repositories
Digestion method	Assessment	III	Digestion methods may liberate metals (e.g., loosely bound or total recovery)	None	Reported by individual studies and data repositories
Analytical method	Exclusion	III	Analytical methods may have different detection limits, analytical error, etc.	ICP or AA	Exclude analytical methods beside ICP or AA with the exception of INAA for some NURE-HSSR samples
Detection limits	Assessment	III	Non-detect results with high detection limits may artificially elevate background levels.	None	Reported by individual studies and data repositories

Note: ArcGIS version to be used in spatial analyses is 10.5.

AA - atomic adsorption
ICP - inductively coupled plasma
in - inch
INAA - instrumental neutron activation analysis
m - meter
mm - millimeter
NA - not applicable
NURE-HSSR - National Uranium Resource Evaluation–Hydrogeochemical and Stream Sediment Reconnaissance
UCR - Upper Columbia River
WRIA - water resource inventory area

[a] Land use code definitions:

87 Public timberland/non-designated forest
88 Designated forest land under chapter 84.33 RCW
89 Other resource production
91 Undeveloped land
92 Noncommercial forest
94 Open space land classified under chapter 84.34 RCW
95 Timberland classified under chapter 84.34 RCW
99 Other undeveloped land

[b] Distinction between features up- and down-gradient of sample locations will support assessment of potential surface runoff and fugitive dust impacts that may affect sample concentrations. The “Flow Length” function in the Hydrology module of the spatial Analyst extension in ArcGIS was used to calculate the distance to upstream features. First, a flow direction raster was created from a digital elevation model using the “Flow Direction” tool. The flow direction raster shows the direction of flow out of each cell. Second, an upstream flow length raster was created using “Flow Length” tool, which calculates the upslope distance along the flow path, from each cell to the upstream features. Lastly, the flow length to upstream features for each location was extracted from the upstream flow length raster based on its spatial location.

[c] Mines and mills considered for this criteria are producers, past producers, plants, or locations designated with an “unknown” development status. Locations with a development status of occurrence (outcrop, shallow pits, or isolated drill holes) or prospect (trenching adits, shafts, characterization) were not considered for this exclusion criteria (e.g., a sample collected < 500 m from an occurrence or prospect is not excluded). For full development status definitions, see USGS (2005).

[d] For the NURE-HSSR dataset, sediments will also be included.

Zinc	Yes	2007[e]	160	120	46	79	46	23,500	46

Notes on following page.

Table 2. Detection limits needed based on conservative risk-based screening values in mg/kg dry weight in soil (continued)

	Ecological Soil Screening Level (ecoSSL)								
TAL Metals	Available	USEPA Document	Terrestrial Plants	Soil Invertebrates	Avian Wildlife	Mammalian Wildlife	Minimum ecoSSL	Human[a]	Maximum Detection Limit (or lower)

Notes:

[a] Except for arsenic, chromium, and four essential nutrients (calcium, magnesium, potassium, and sodium) screening levels are conservative risk-based concentrations calculated using EPA's Regional Screening Level Calculator (http://epa-prgs.ornl.gov/cgi-bin/chemicals/csl_search) and default values for residential exposure factors. The screening level for arsenic is based on the Washington cleanup level (20 mg/kg) and was established as the project action limit for arsenic in the 2014 residential soils study. There is no human health screening level for total chromium.

[b] No numeric ecoSSLs. Aluminum identified as of potential concern only for soils with a soil pH < 5.5.

[c] Insufficient data to derive soil screening values.

[d] No numeric ecoSSLs. Iron identified as of concern as a mediator in the geochemistry of other metals and the potential physical hazard of depositing iron floc.

[e] The EPA screening value for lead (400 mg/kg) incorporates a default relative bioavailability (RBA) assumption and is not directly comparable to measured lead as reported by the analytical laboratory without adjustment for RBA. The State of Washington has adopted a screening level for lead of 250 mg/kg, which is the value that was reported to landowners in letters summarizing their residence-specific study results.

[f] Vanadium ecoSSL report is interim final.

[g] Calcium, magnesium, potassium, and sodium are toxic to wildlife in the percent range, and therefore the detection limit from any type of soil analysis that is less than 10,000 mg/kg is acceptable (NRC 2005).

[h] Soil mercury is in the inorganic form. According to NRC (2005), diets with "0.2 mg/kg is tolerated by rodents, poultry, and pigs".

[i] The maximum detection limit allowable for thallium is based on the U.S. Army's Wildlife Toxicity Assessment for Thallium (USACHPPM 2007) which has a rat-based toxicity reference values (TRV) derived from exposure of 10 ppm thallium in drinking water with additional uncertainty factors. The lowest-observed-adverse-effect level [LOAEL] uncertainty factor of 4 and NOAEL uncertainty factor of LOAEL/10). This results in 2.5 ppm for LOAEL and 0.25 ppm for NOAEL, thus 0.25 mg/kg would be conservative choice for the maximum allowed detection limit. No information was found for birds, invertebrates, or plants.

mg/kg – milligram(s) per kilogram(s)

Attachment A-2

TAI Responses to EPA's Consolidated Comments (TAI 2018a)

Comment Number	Comment	Type	TAI Response
General Comments			
1	The draft document notes that results from the background soil assessment will inform future tasks related to assessing ecological and human health risks. Describe more concretely the specific RI/FS-related uses for this background soil data.	Additional detail	**Specific RI/FS Use for Background Soil Data** **Ecological Risk Assessment:** Soil conditions, including concentrations of metal, minerals, and nutrients, are major determinants of plant communities (other determinants include, but are not limited to, soil moisture, soil texture, temperature, and sunlight). Therefore, it is not possible to conclude "risk" to plant communities if metals, minerals, and nutrients are at natural background levels, even if these concentrations are higher than those determined through laboratory toxicity tests to result in phytotoxicity in test species. Species that are sensitive to certain metals, minerals, or nutrients simply will not be present in areas that have naturally high concentrations of these substances. Plant communities, in turn, are determinants of animal (invertebrate and vertebrate) communities, which also should not be considered at risk when soils concentrations are at naturally occurring levels. Knowledge of natural background concentrations in upland soils at the Upper Columbia River (UCR) Site (the Site) can be applied during the RI/FS process by removing from further consideration areas where measured soil concentrations of the contaminants of potential concern are no higher than natural background. Areas where concentrations are higher than natural background will be further evaluated to determine which species/communities are likely to be at risk from the elevated concentrations of metals or minerals. **Human Health Risk Assessment:** Understanding natural and area background concentrations is essential to distinguishing the potential for risk associated with the Site from risks unrelated to the Site. Consistent with U.S. Environmental Protection Agency (EPA) guidance, risks associated with natural and area background concentrations should be discussed in the risk characterization of the baseline human health risk assessment (BHHRA) by describing the contribution of background risks to cumulative risks (USEPA 2002). Human health risks based on the natural background concentrations developed in the background assessment will be compared to risks estimated for decision units (DUs) evaluated in the residential soil study. In areas where background risks are greater than those associated with the Site, the background concentrations will be used to refine numeric cleanup levels for those specific chemicals of concern (COCs), as cleanup levels cannot be set at concentrations below area or natural background concentrations. USEPA. 2002. Appendix B, Policy considerations for the application of background data in risk assessment and remedy selection, Role of background in the CERCLA cleanup program. OSWER 9285.6-07P. In: Guidance for Comparing Background and Chemical Concentrations in Soil for CERCLA Sites. EPA 540-R-01-003, OSWER 9285.7-41. U.S. Environmental Protection Agency, Office of Solid Waste and Emergency and Remedial Response, Washington, DC. September.

Comment Number	Comment	Type	TAI Response
2	The BERA workplan is not specific about which "background" will be used for comparison if unacceptable risks are determined. The DQO document needs to identify what kind of background is being defined ("area" versus "natural") and whether different types of background are needed for the different RI/FS and risk assessment tasks, or if an effort will be made to determine site-specific background with comparable natural and anthropogenic variability. Given that there are other sources of metals in the area, it makes sense to determine area background as well as geological (natural) background from non-site related anthropogenic (area) background.	Additional detail	The analysis will determine natural background as per the definition in the Washington State Model Toxics Control Act. This includes anthropogenic influence of large-scale diffuse sources (e.g., mercury; PCBs, dioxin), but eliminates local or point source anthropogenic input. The area to be evaluated in the background assessment is a large, heterogeneous area, which makes it difficult to account generally for local anthropogenic inputs. Therefore, as detailed in the data quality objectives (DQOs), soil data from areas such as in or near, roads, railroads, mines, mills will not be used. Similar to the approach presented by the EPA in the "level of effort" memorandum (USEPA 2016) that outlined an approach to compiling a background dataset from preexisting data sources along with DQO Steps 1to 3 for that process, soil data within the area delineated as injured by sulfur dioxide (SO_2) in the 1920s–1930s (Scheffer and Hedgcock 1955) will be avoided to remove the potential for deposition from Trail and LeRoi/Northport smelters. The area serves as a convenient exclusion zone for selecting background samples within the Site, away from areas affected by historical emissions from both the Trail and LeRoi/Northport smelter stacks without the use of air dispersion and deposition modeling. The remaining areas from which soil measurements will be used for background determination are remote from human influence and can be considered natural background. The DQOs are focused on defining natural background concentrations only, largely supporting the baseline ecological risk assessment (BERA), and do not address local area, or anthropogenic, background concentrations. While determination of natural background will be useful to both the BERA and BHHRA, the BHHRA also must consider anthropogenic *influences* on a localized scale affecting residential properties, which is an issue that will be addressed apart from defining the natural background levels. For example, the residential soil sampling and removal efforts documented discarded lead acid batteries, presence of treated wood, domestic waste incineration, past pesticide use, and other human sources of contamination to Site upland soils that are unrelated to historical aerial deposition of metals from smelter emissions or the presence of mineralized soils. The influence of human sources and activities contributes to "area" background concentrations, particularly for lead and arsenic, and must be considered on a case-by-case basis for those properties where measured metals concentrations in soil are greater than natural background. Scheffer, T.C., and G.G. Hedgcock. 1955. Injury to northwestern forest trees by sulfur dioxide from smelters. Technical Bulletin 1117. U.S. Department of Agriculture, Economic Research Service, Washington, DC. USEPA. 2016. EPA level of effort (LOE) for assessment and estimations of upland soils - Upper Columbia River Basin. U.S. Environmental Protection Agency, Technical Team. July.

Comment Number	Comment	Type	TAI Response
3	Provide basis for developing background concentrations for all 23 metals and metalloids. Some metals are essential nutrients and not risk drivers (e.g., calcium, magnesium, sodium, potassium, etc.). If Teck proposes using these additional metals for purposes of estimating soil cation exchange capacity or otherwise, such intended uses should be defined in the DQOs.	Study design	Knowledge about natural background soil concentrations is needed to assess risks to any inorganic substances of concern in the UCR uplands, as described in response to General Comment 1. We began with the 23 target analyte list (TAL) metals, which were agreed upon by Teck American Incorporated (TAI) and EPA as those that would be quantified in the Upland Soil Sampling QAPP (TAI 2014) for risk determination. The TAL was derived from EPA's Priority Pollutants list of 126 metal and organic substances, which are a subset of the "toxic pollutants" as defined in the Clean Water Act. The Priority Pollutants were those frequently found in wastewater, and the 23 TAL metals are those also frequently encountered at hazardous waste sites. The list was developed for aquatic systems, hence the inclusion of aluminum and iron, which are among the most abundant elements in the earth's crust). Aluminum and iron are highly unlikely to cause toxicity in terrestrial systems. The TAL contains some plant-associated nutrients (although nitrogen and phosphorus are notably missing) presumably, because they, too, are frequently elevated in wastewater and at contaminated aquatic sites. If EPA concurs that it is not necessary to assess ecotoxicological risks associated with plant nutrients in the upland soils, then those elements should be removed from the list of terrestrial chemicals of interest for the UCR RI/FS. There is value, however, in retaining potassium, magnesium, calcium, and sodium for further analysis in the BERA. Cation exchange capacity (CEC) is calculated from concentration data for these elements and hydrogen (pH) in soils. Thus, the CEC also can be used (along with pH) to understand the natural bioavailability of metals in soils from the area of interest. TAI. 2014. Upper Columbia River, final soil study quality assurance project plan. Prepared by Exponent, Bellevue, WA, and HDR, Mahwah, NJ, in association and consultation with Parametrix, Inc., Bellevue, WA, and Cardwell Consulting LLC, Corvallis, OR. Teck American Incorporated, Spokane, WA. August.

Comment Number	Comment	Type	TAI Response
4	The term "mineralized area" is used with little specificity. Define “mineralized area”.	Additional detail	For this study, “mineralized areas” are metal/loid deposits identified by the U.S. Geological Survey (USGS) Mineral Resources Data System (MRDS)[1] occurrences, prospects, active/inactive mines, and processing facilities.[2] The 500-m setback for sample selection will be applied to mines and processing facilities. When calculating the distance to the nearest occurrences, prospects, active/inactive mines, and processing facilities, we also added the name of the site and the commodity code[3] used (e.g., AU, PB, CU). We will review these for sites within 500-m to see we are over screening (i.e., excluding samples in areas with non-metallic commodities like pumice or gravel). [1] “MRDS is a collection of reports describing metallic and nonmetallic mineral resources throughout the world. Included are deposit name, location, commodity, deposit description, geologic characteristics, production, reserves, resources, and references.” https://mrdata.usgs.gov/mrds/ [2] For definitions see https://mrdata.usgs.gov/metadata/mrds.html [3] For definitions see https://mrdata.usgs.gov/mrds/commodity-codes.html
5	Elaborate on the criteria considered to deem a data set acceptable for establishing natural and/or area background (e.g., location relative to known sources, sample depth, target analytes, analytical methods)	Additional detail	The draft final DQO includes a new table, Table 1, which summarizes the criteria that will be used in the assessment.

Comment Number	Comment	Type	TAI Response
6	Limiting samples to those 6 inches and shallower may be unnecessarily restrictive. Although it is true that surface soils are of greatest interest, these are also most likely to be impacted by other sources that may alter concentrations. It might be beneficial to consider shallow subsurface data (6-18 inches) as additional verification data for the surface. If there is no difference between surface and subsurface (i.e., surface is not higher than subsurface), this will support a conclusion that surface samples represent background. However, if surface is greater, this might suggest contamination from some other source.	Study design	**Limiting Samples to the Upper 6 Inches of Soil:** Plants receive most of their nutrients from the soil A Horizon, which is where most soil invertebrates live as well (although some live only in the litter layer on top of the soil). Therefore, risk to terrestrial systems from metal contamination is primarily restricted to concentrations in the A Horizon, i.e., the top 6 inches of soil. While it is tempting to assume that the A Horizon should have similar metal concentrations to the subsoil horizon (e.g., the B Horizon at the 6 to 18 inches depth) in natural areas, there are many reasons why this might not be the case. These include decomposition of plant material, which changes pH, organic/clay ratios, and mobilization of metals and surface movement of topsoil from erosion and/or flooding. The B Horizon is of little to no interest from an ecological perspective, so measurements of the metals concentrations in subsoils would only add uncertainty (if different from surface soils) and not resolve the issue of natural background concentrations. WAC 173-340-200 defines "natural background" as "the concentration of hazardous substance consistently present in the environment that has not been influenced by localized human activities." Methods for defining natural background concentrations are provided in WAC 173-340-709. Comparing soil horizons is not among the methods. WAC 173-340-709 stipulates that comparative samples should have the same basic characteristics as the (soil) of concern at the site, which precludes comparing soil horizons because they have different basic characteristics for the reasons noted above. **Avoiding Contamination from Anthropogenic Sources:** The background dataset will be carefully evaluated to confirm the samples represent a single consistent population without outliers, as explained in DQO Step 5 where it discusses how background threshold values will be derived for the background assessment.

Comment Number	Comment	Type	TAI Response
7	The analytic approach only mentions calculating the "95th UTL". The LOE specified that "For COI/COPCs and elements of interest, the minimum, maximum, mean, median geometric mean, and an upper percentile of the distribution will be estimated at a minimum, along with upper confidence limits where appropriate." Include these additional summary statistics in the Step 5 analytical approach. Additionally, geospatial analysis alone is not adequate to determine if sample results are representative of background. Include use of statistical tests to identify and exclude outliers.	Analytical approach	Complete output from the ProUCL software will be included in the background assessment report, providing all of the summary statistics listed in addition to goodness-of-fit distributional assessments and various statistics for consideration as background threshold value using multiple methods for handling undetected results. The report will include maps showing concentrations overlaid with geospatial classifications, including drainage boundaries, geological classifications, and locations of anthropogenic alternations or disturbances. Analysis of variance will be used to identify significant differences between the various geospatial categories.
8	The use of footnotes to list references as well as additional information is inconsistent with previous UCR documents. The reader would benefit from the addition of a references section and deletion of reference listings in the footnotes.	Editorial	References have been moved into a reference section in the DQO document and the referenced footnotes deleted.

Comment Number	Comment	Type	TAI Response
Specific Comments			
1	DQO Step 3, Pages 4 & 5. The list proposes the use of Ecology's EIM. Any data potentially being identified from this database will require extensive review of the nature and appropriateness of the data collected. A clear demonstration and application that the data found are appropriate for background purposes will be required. The vast majority of EIM data were collected from contaminated cleanup sites, not areas appropriate for developing natural background.	Study Design	The sample data selected for the background assessment will be screened using the criteria for avoiding contamination from anthropogenic sources, other than large-scale diffuse sources, detailed in DQO Table 1 (new) prepared for General Comment 5. TAI expects that by applying these criteria, samples from contaminated sites will be removed from consideration. In addition, project documents for samples from EIM that are not screened out will be reviewed for appropriateness as with any other study included in the background dataset.
2	DQO Step 3, Pages 4 & 5. Geographic study boundaries are a significant consideration. The proposed list includes online Canadian data sets. Unless the data being sought are from soil samples collected in NE Washington State, these Canadian data bases should be removed as potential data sources. This comment was rescinded in an email from EPA (2018), which stated, "Upon further consideration, we view background data from Canada in the vicinity of the Trail Smelter to be representative of local conditions. Data from Canada should therefore be included as potential data sources."	Study Design	TAI has reviewed the two Canadian datasets referred to in the preliminary draft DQO document dated June 1, 2018, i.e., the British Columbia Soil Information System (BCSIS) and British Columbia Ministry of the Environment (BCME) background soil data. For areas north of the Washington State Water Resource Inventory Areas (WRIAs) referred to in General Comment 3, none of the samples from BCSIS were collected from the A Horizon. The BCME background dataset includes surficial samples near 19 cities and towns in the Southern Interior and Kootenay ministry regions of British Columbia. Although some of these (e.g., Trail, Creston, Castlegar, Nelson) may be useful for the delineation study, others are in different physiographic regions and geologic settings, and far afield to be considered representative of background conditions of UCR upland areas. Thus, TAI has removed these datasets from further consideration for the background assessment.

Comment Number	Comment	Type	TAI Response
3	DQO Step 5, Page 5, Geographic scope and boundaries need to be set and acknowledged to manage the extent of data gathering and management. Consider limiting search to samples in the following 11 Water Resource Inventory Areas (WRIAs) connected to the UCR: WRIAs 49, 51, 52, 53, 54, 55, 58, 59, 60, 61, and 62.	Study Design	The revised draft final DQO indicates that the data used in the background assessment will be limited to the WRIAs listed in this comment.
4	DQO Step 4, Page 5. How will TAI determine if soils have been influenced by the LeRoi/Northport smelters? If the intent is to determine which data represent background (presuming natural) and have not been influenced by the Le Roi/Northport smelters (area) it is necessary to establish the area background. Will there be a range in area background as compared to natural background? Some explanation on the intent and process here would be helpful.	Clarification	Area background in the vicinity of Northport would vary by distance and direction away from the site of the former LeRoi/Northport smelter. Selecting samples outside the aerial influence of the LeRoi/Northport smelter is important for assembling a dataset from which natural background concentrations may be calculated. Emissions from the LeRoi/Northport smelter likely followed the same topographic pathway along the river as the area mapped for forest injury shown in Scheffer and Hedgcock (1955). Thus, TAI expects that by excluding samples from the SO_2 injury areas (Zones 1 to 3), most, if not all, the contamination from the LeRoi/Northport smelter should be excluded. Scheffer, T.C., and G.G. Hedgcock. 1955. Injury to northwestern forest trees by sulfur dioxide from smelters. Technical Bulletin 1117. U.S. Department of Agriculture, Economic Research Service, Washington, DC.
5	DQO Step 5, Page 6, Footnote 16. Regarding NURE sediment samples collected from tributary locations, samples collected from UCR tributary streams, whether wet or dry are useful to establishing background and should not be excluded because of conditions at the time of sampling.	Study Design	National Uranium Resource Evaluation (NURE) sediment and soil samples that pass the screening criteria summarized on DQO Table 1 (new; see General Comment 5) will be considered for the background dataset.

Comment Number	Comment	Type	TAI Response
6	DQO Step 5, Page 6 (first bullet, sub-bullet 4 and footnote 17). Describe how Tier 1 screening for undeveloped areas would be performed and how that screening differs from the specific screening criteria listed under Tier II.	Clarification	Removed sub-bullet from Tier I. See Table 1 for details on identification of undeveloped areas.
7	DQO step 5, Page 7. Include date of collection and analytical suite in Tier III in key sampling information.	Additional detail	Date of collection and analytical suite (for metals and metalloids only) have been added to Tier III.
8	DQO Step 5, Page 7. Describe what specific geospatial platform, methodology and criteria will be applied to the data, and what decision criteria will determine data pooling or segregation. Additionally, describe statistical tests to be used to identify and exclude outliers.	Analytical approach	The geospatial platform used is ArcGIS 10.5 with the Spatial Analyst extension. The "Flow Length" function in the Hydrology module of the Spatial Analyst extension in ArcGIS 10.5 was used to calculate the distance to upstream features. Additional details are in DQO Table 1 (new) (see General Comment 5). Analysis of variance will be used to identify significant differences between the various geospatial designations. Outlier tests will include Dixon and Rosner tests, depending on the number of samples, in addition to quantile-quantile plots based on as-measured and log-transformed concentrations.
9	DQO Step 6, Page 9. The draft DQOs propose that only ICP or AA data will be carried forward. This is not an appropriate restriction, as some metals evaluated under other analytic methods also apply. For example, Neutron Activation methods used in Savannah NURE labs are representative and defensible for selected metals of interest--specifically Al, Fe, and Mn.	Study design	For the USGS NURE-HSSR dataset, element concentrations measured by neutron activation by Savannah River National Laboratory will also be considered.
10	DQO Step 6, Page 9, 2nd bullet. Appropriate detection limits based on conservative risk-based screening values should be listed in a table. Also, suggest that these be described as screening values and not risk values.	Additional detail	The suggested revision has been made in the text of the revised DQOs and a new table was added. Table lists the ecological soil screening levels, human health soil risk-based concentrations, and appropriate detection limits.

Comment Number	Comment	Type	TAI Response
11	DQO Step 7, Page 10. The page following page 9 is labeled page 2 but should be page 10.	Editorial	Edit made.
12	Attachment A. There are some sections in the attachment with poorly explained sources (e.g., documents listed under the "Report Not Seen" and "Report Seen" headings). It is not apparent how data from these sources are to be used and evaluated.	Clarification	List has been revised for clarity. Also, studies that are sediment only have been removed from this list.

Subject: FW: UCR-Background Assessment DQO's - final comments

Kris,

We have no further comment of the Draft Final Background Assessment DQOs.

Thank you

Kathryn Cerise
UCR RPM

Attachment B

Assessment of Methods of Sample Preparation and Analysis

Attachment B
Assessment of Methods of Sample Preparation and Analysis

The methods of sample preparation and analysis were researched for each of the studies in the Tier IIIA dataset. These generally fit into four categories: total metals, partial digestion (also known as total-recoverable), loss on ignition (LOI) plus digestion, and mercury (see discussion in Section 2.3.6.1). Boxplots were made for each metal and metalloid by sample preparation method. In addition, each study is offset within each method group and the size fractions are represented by different symbols. The boxplots are included below. For many of the metals and metalloids, concentrations vary by sample preparation method and by study.

Statistical comparisons between the sample preparation methods (irradiated neutron activation analysis, total digestion, LOI+digestion, and partial digestion) also identified differences in concentrations, although there are other differences between the studies that confound interpretation of differences as only due to sample preparation. Table B-1 summarizes output from non-parametric Kruskal-Wallis and parametric analysis of variance (ANOVA) comparisons between preparation categories. The parametric ANOVA used log-transformed concentrations to better meet the underlying assumptions and Tukey's honest significant difference (HSD) to identify which categories differed at an overall 0.01 significance level after accounting for multiple comparisons.[1]

The boxplots and statistical comparisons indicate significant differences in concentrations between the preparation methods. Additionally, the studies shown on the boxplots and included in the statistical comparisons also reflect differences in sieving and physical location (multiple Washington State Water Resource Inventory Areas [WRIAs]). Although these differences exist, all sample preparation methods remained in the dataset to expand the geographical range and size of the dataset.

Zinc	<1.0E-15	<1.0E-15		a	b	b		Lowest	Highest	Middle

Notes: [a] Rankings based on median of log-transformed concentrations

Mercury was only measured by a one method class, therefore no comparisons were possible.
Multiple comparisons between method classes by Tukey's honest significant difference (HSD) at an overall 0.01 significance level (i.e., 99% confidence level The letters have no inherent meaning and are simply used to designate method classes that are similar or significantly different. Method classes not significantly different are indicated with the same letter.

ANOVA - analysis of variance
HSD - Tukey's honest significant difference
INAA - irradiated neutron activation analysis
LOI - loss on ignition
Partial Digestion - partial digestion methods
Total Digestion - total digestion methods

Notes on following page.

Table C-1. (Continued)

Notes: [a] Concentrations below detection limits are included at the result specific detection limit

[b] High concentration outliers determined from visual inspection of QQ-plots and formal outlier tests (Dixon or Rosner) based on log-transformed concentrations except antimony and thallium (follow a normal distribution, therefore measured concentrations used) with ND results excluded

[c] BTV is higher than the maximum detected concentration.

Arith. Mean	- arithmetic mean
BTV	- background threshold value (rounded to three significant figures or two significant figures if less than 10 mg/kg)
DQOs	- data quality objectives
Geo. Mean	- geometric mean
KM	- Kaplan-Meier
Max(Det)	- maximum of detected concentrations
Min(Det)	- minimum of the detected concentrations
Min(ND)	- minimum of the specified detection limits
N	- number of samples
NA	- not applicable
ND	- number of samples with concentrations below the detection limit
w/o 2 outliers	- values calculated without 2 highest concentration outliers; minimum number of outliers identified by QQ-plots and tests.

Table C-2. Background threshold values for screened background samples analyzed by partial digestion and mercury methods

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	256	Mean	59059

Nonparametric Distribution Free Background Statistics
Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	3011	95% UTL with95% Coverage	73800
Approx, f used to compute achieved CC	1.148	Approximate Actual Confidence Coefficient achieved by UT	0.95
Approximate Sample Size needed to achieve specified CC	3147	95% UPL	73300
95% USL	105500	95% KM Chebyshev UPL	108399

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics
Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	67	95% UTL with95% Coverage	2
Approx, f used to compute achieved CC	1.763	Approximate Actual Confidence Coefficient achieved by UT	0.86
Approximate Sample Size needed to achieve specified CC	93	95% UPL	2
95% USL	9	95% KM Chebyshev UPL	5.068

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics
Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	2964	95% UTL with95% Coverage	52480
Approx, f used to compute achieved CC	1.147	Approximate Actual Confidence Coefficient achieved by UT	0.948
Approximate Sample Size needed to achieve specified CC	3104	95% UPL	51200
95% USL	109700	95% KM Chebyshev UPL	79728

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics
Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	817	95% UTL with95% Coverage	6
Approx, f used to compute achieved CC	1.265	Approximate Actual Confidence Coefficient achieved by UT	0.926
Approximate Sample Size needed to achieve specified CC	877	95% UPL	5
95% USL	29	95% KM Chebyshev UPL	12.68

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Approximate Sample Size needed to achieve specified CC	854	95% UPL	1
95% USL	19.3	95% KM Chebyshev UPL	4.179

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	79.77

Outlier Tests for Selected Variables excluding nondetects

Dixon's Outlier Test for LNmeas_value_update (total, cadmium)

Total N = 68
Number NDs = 61
Number Detects = 7
10% critical value: 0.434
5% critical value: 0.507
1% critical value: 0.637
Note: NDs excluded from Outlier Test

1. Data Value 2.19722457733622 is a Potential Outlier (Upper Tail)?

Test Statistic: 0.759

For 10% significance level, 2.19722457733622 is an outlier.
For 5% significance level, 2.19722457733622 is an outlier.
For 1% significance level, 2.19722457733622 is an outlier.

2. Data Value -1.6094379124341 is a Potential Outlier (Lower Tail)?

Test Statistic: 0.107

For 10% significance level, -1.6094379124341 is not an outlier.
For 5% significance level, -1.6094379124341 is not an outlier.
For 1% significance level, -1.6094379124341 is not an outlier.

95% Chebyshev UPL	17.2	99% Percentile	14.01
95% USL	19.15		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.298	Mean	1.664

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics
Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	66	95% UTL with95% Coverage	2
Approx, f used to compute achieved CC	1.737	Approximate Actual Confidence Coefficient achieved by UTL	0.854
Approximate Sample Size needed to achieve specified CC	93	95% UPL	2
95% USL	2	95% KM Chebyshev UPL	0.77

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics
Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	811	95% UTL with95% Coverage	30
Approx, f used to compute achieved CC	1.255	Approximate Actual Confidence Coefficient achieved by UTL	0.919
Approximate Sample Size needed to achieve specified CC	877	95% UPL	30
95% USL	70	95% KM Chebyshev UPL	48.79

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	184.9	99% Percentile	157
95% USL	364		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	3.155	99% Percentile	2.49
95% USL	3		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	35.04	99% Percentile	24.5
95% USL	24.6		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.08	Mean	0.0837
Maximum	0.09	Median	0.0835

95% Chebyshev UPL	0.0891	99% Percentile	0.0498
95% USL	0.05		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% USL	98.4		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.007	Mean	0.0639

Nonparametric Distribution Free Background Statistics
Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	102	95% UTL with95% Coverage	0.14
Approx, f used to compute achieved CC	1.789	Approximate Actual Confidence Coefficient achieved by UT	0.897
Approximate Sample Size needed to achieve specified CC	124	95% UPL	0.118
95% USL	2.81	95% KM Chebyshev UPL	1.257

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.
